[...] The goal of structural complexity is a thorough understanding of the relations between the various complexity classes and the internal structure of these complexity classes." [J. Hartmanis]

Decision Problems

- Have answers of the form "yes" or "no"
- Encoding: each instance $x$ of the problem is represented as a string of an alphabet $\Sigma(|\Sigma| \geq 2)$.
- Decision problems have the form "Is $x$ in $L$ ?", where $L$ is a language, $L \subseteq \Sigma^{*}$.
- So, for an encoding of the input, using the alphabet $\Sigma$, we associate the following language with the decision problem $\Pi$ :
$L(\Pi)=\left\{x \in \Sigma^{*} \mid x\right.$ is a representation of a "yes" instance of the problem $\left.\Pi\right\}$

## Example

- Given a number $x$, is this number prime? $(x \stackrel{?}{\in}$ PRIMES)
- Given graph $G$ and a number $k$, is there a clique with $k$ (or more) nodes in $G$ ?

## Optimization Problems

- For each instance $x$ there is a set of Feasible Solutions $F(x)$.
- To each $s \in F(x)$ we map a positive integer $c(x)$, using the objective function $c(s)$.
- We search for the solution $s \in F(x)$ which minimizes (or maximizes) the objective function $c(s)$.

## Example

- The Traveling Salesperson Problem (TSP): Given a finite set $C=\left\{c_{1}, \ldots, c_{n}\right\}$ of cities and a distance $d\left(c_{i}, c_{j}\right) \in \mathbb{Z}^{+}, \forall\left(c_{i}, c_{j}\right) \in C^{2}$, we ask for a permutation $\pi$ of $C$, that minimizes this quantity:

$$
\sum_{i=1}^{n-1} d\left(c_{\pi(i)}, c_{\pi(i+1)}\right)+d\left(c_{\pi(n)}, c_{\pi(1)}\right)
$$

## A Model Discussion

- There are many computational models (RAM, Turing Machines etc).
- The Church-Turing Thesis states that all computation models are equivalent. That is, every computation model can be simulated by a Turing Machine.
- In Complexity Theory, we consider efficiently computable the problems which are solved (aka the languages that are decided) in polynomial number of steps (Edmonds-Cobham Thesis).

## Definition

A Turing Machine $M$ is a quintuple $M=\left(Q, \Sigma, \delta, q_{0}, F\right)$ :

- $Q=\left\{q_{0}, q_{1}, q_{2}, q_{3}, \ldots, q_{n}, q_{\text {yes }}, q_{\mathrm{no}}\right\}$ is a finite set of states.
- $\Sigma$ is the alphabet. The tape alphabet is $\Gamma=\Sigma \cup\{\sqcup\}$.
- $q_{0} \in Q$ is the initial state.
- $F \subseteq Q$ is the set of final states.
- $\delta:(Q \backslash F) \times \Gamma \rightarrow Q \times \Gamma \times\{S, L, R\}$ is the transition function.
- A TM is a "programming language" with a single data structure (a tape), and a cursor, which moves left and right on the tape.
- Function $\delta$ is the program of the machine.

## Turing Machines and Languages

Definition
Let $L \subseteq \Sigma^{*}$ be a language and $M$ a TM such that, for every string $x \in \Sigma^{*}$ :

- If $x \in L$, then $M(x)=$ "yes"
- If $x \notin L$, then $M(x)=$ "no"

Then we say that $M$ decides $L$.

- Alternatively, we say that $M(x)=L(x)$, where $L(x)=\chi_{L}(x)$ is the characteristic function of $L$ (if we consider 1 as "yes" and 0 as "no").
- If $L$ is decided by some TM $M$, then $L$ is called a recursive language.

## Definition

If for a language $L$ there is a TM $M$, which if $x \in L$ then $M(x)=$ "yes", and if $x \notin L$ then $M(x) \uparrow$, we call $L$ recursively enumerable.
*By $M(x) \uparrow$ we mean that $M$ does not halt on input $x$ (it runs forever).
Theorem
If $L$ is recursive, then it is recursively enumerable.
Proof: Exercise

Definition
If for a language $L$ there is a TM $M$, which if $x \in L$ then
$M(x)=$ "yes", and if $x \notin L$ then $M(x) \uparrow$, we call $L$ recursively enumerable.
*By $M(x) \uparrow$ we mean that $M$ does not halt on input $x$ (it runs forever).
Theorem
If $L$ is recursive, then it is recursively enumerable.
Proof: Exercise
Definition
If $f$ is a function, $f: \Sigma^{*} \rightarrow \Sigma^{*}$, we say that a TM $M$ computes $f$ if, for any string $x \in \Sigma^{*}, M(x)=f(x)$. If such $M$ exists, $f$ is called a recursive function.

- Turing Machines can be thought as algorithms for solving string related problems.

## Multitape Turing Machines

- We can extend the previous Turing Machine definition to obtain a Turing Machine with multiple tapes:

Definition
A k-tape Turing Machine $M$ is a quintuple $M=\left(Q, \Sigma, \delta, q_{0}, F\right)$ :

- $Q=\left\{q_{0}, q_{1}, q_{2}, q_{3}, \ldots, q_{n}, q_{\text {halt }}, q_{\text {yes }}, q_{\mathrm{no}}\right\}$ is a finite set of states.
- $\Sigma$ is the alphabet. The tape alphabet is $\Gamma=\Sigma \cup\{\sqcup\}$.
- $q_{0} \in Q$ is the initial state.
- $F \subseteq Q$ is the set of final states.
- $\delta:(Q \backslash F) \times \Gamma^{k} \rightarrow Q \times(\Gamma \times\{S, L, R\})^{k}$ is the transition function.

## Bounds on Turing Machines

- We will characterize the "performance" of a Turing Machine by the amount of time and space required on instances of size $n$, when these amounts are expressed as a function of $n$.

Definition
Let $T: \mathbb{N} \rightarrow \mathbb{N}$. We say that machine $M$ operates within time $T(n)$ if, for any input string $x$, the time required by $M$ to reach a final state is at most $T(|x|)$. Function $T$ is a time bound for $M$.

## Definition

Let $S: \mathbb{N} \rightarrow \mathbb{N}$. We say that machine $M$ operates within space $S(n)$ if, for any input string $x, M$ visits at most $S(|x|)$ locations on its work tapes (excluding the input tape) during its computation. Function $S$ is a space bound for $M$.

## Multitape Turing Machines

Theorem
Given any k-tape Turing Machine $M$ operating within time $T(n)$, we can construct a TM $M^{\prime}$ operating within time $\mathcal{O}\left(T^{2}(n)\right)$ such that, for any input $x \in \Sigma^{*}, M(x)=M^{\prime}(x)$.

Proof: See Th. 2.1 (p.30) in [1].

- This is a strong evidence of the robustness of our model: Adding a bounded number of strings does not increase their computational capabilities, and affects their efficiency only polynomially.

## Linear Speedup

## Theorem

Let $M$ be a TM that decides $L \subseteq \Sigma^{*}$, that operates within time $T(n)$. Then, for every $\varepsilon>0$, there is a $T M M^{\prime}$ which decides the same language and operates within time $T^{\prime}(n)=\varepsilon T(n)+n+2$.

Proof: See Th. 2.2 (p.32) in [1].

- If, for example, $T$ is linear, i.e. something like $c n$, then this theorem states that the constant $c$ can be made arbitrarily close to 1 . So, it is fair to start using the $\mathcal{O}(\cdot)$ notation in our time bounds.
- A similar theorem holds for space:

## Theorem

Let $M$ be a TM that decides $L \subseteq \Sigma^{*}$, that operates within space $S(n)$. Then, for every $\varepsilon>0$, there is a $T M M^{\prime}$ which decides the same language and operates within space $S^{\prime}(n)=\varepsilon S(n)+2$.

## Nondeterministic Turing Machines

- We will now introduce an unrealistic model of computation:

Definition
A Turing Machine $M$ is a quintuple $M=\left(Q, \Sigma, \delta, q_{0}, F\right)$ :

- $Q=\left\{q_{0}, q_{1}, q_{2}, q_{3}, \ldots, q_{n}, q_{\text {halt }}, q_{\mathrm{yes}}, q_{\mathrm{no}}\right\}$ is a finite set of states.
- $\Sigma$ is the alphabet. The tape alphabet is $\Gamma=\Sigma \cup\{\sqcup\}$.
- $q_{0} \in Q$ is the initial state.
- $F \subseteq Q$ is the set of final states.
- $\delta:(Q \backslash F) \times \Gamma \rightarrow \operatorname{Pow}(Q \times \Gamma \times\{S, L, R\})$ is the transition relation.

## Nondeterministic Turing Machines

- In this model, an input is accepted if there is some sequence of nondeterministic choices that results in "yes".
- An input is rejected if there is no sequence of choices that lead to acceptance.
- Observe the similarity with recursively enumerable languages.

Definition
We say that $M$ operates within bound $T(n)$, if for every input $x \in \Sigma^{*}$ and every sequence of nondeterministic choices, $M$ reaches a final state within $T(|x|)$ steps.

- The above definition requires that $M$ does not have computation paths longer than $T(n)$, where $n=|x|$ the length of the input.
- The amount of time charged is the depth of the computation tree.

## Diagonalization

Suppose there is a town with just one barber, who is male. In this town, the barber shaves all those, and only those, men in town who do not shave themselves. Who shaves the barber?
Diagonalization is a technique that was used in many different cases:

George showed it wouldn't fit in.

## Diagonalization

## Theorem <br> The functions from $\mathbb{N}$ to $\mathbb{N}$ are uncountable.

Proof: Let, for the sake of contradiction that are countable: $\phi_{1}, \phi_{2}, \ldots$. Consider the following function: $f(x)=\phi_{x}(x)+1$. This function must appear somewhere in this enumeration, so let $\phi_{y}=f(x)$. Then $\phi_{y}(x)=\phi_{x}(x)+1$, and if we choose $y$ as an argument, then $\phi_{y}(y)=\phi_{y}(y)+1 . \square$

## Diagonalization

## Theorem <br> The functions from $\mathbb{N}$ to $\mathbb{N}$ are uncountable.

Proof: Let, for the sake of contradiction that are countable: $\phi_{1}, \phi_{2}, \ldots$. Consider the following function: $f(x)=\phi_{x}(x)+1$. This function must appear somewhere in this enumeration, so let $\phi_{y}=f(x)$. Then $\phi_{y}(x)=\phi_{x}(x)+1$, and if we choose $y$ as an argument, then $\phi_{y}(y)=\phi_{y}(y)+1$. $\square$

- Using the same argument:

Theorem
The functions from $\{0,1\}^{*}$ to $\{0,1\}$ are uncountable.

## Machines as strings

- It is obvious that we can represent a Turing Machine as a string: just write down the description and encode it using an alphabet, e.g. $\{0,1\}$.
- We denote by $L M\lrcorner$ the TM M's representation as a string.
- Also, if $x \in \Sigma^{*}$, we denote by $M_{x}$ the TM that $x$ represents.

## Keep in mind that:

- Every string represents some TM.
- Every TM is represented by infinitely many strings.
- There exists (at least) a noncomputable function from $\{0,1\}^{*}$ to $\{0,1\}$, since the set of all TMs is countable.

## The Universal Turing Machine

- So far, our computational models are specified to solve a single problem.
- Turing observed that there is a TM that can simulate any other TM $M$, given M's description as input.

Theorem
There exists a TMU such that for every $x, w \in \Sigma^{*}$, $\mathcal{U}(x, w)=M_{w}(x)$.
Also, if $M_{w}$ halts within $T$ steps on input $x$, then $\mathcal{U}(x, w)$ halts within $C T \log T$ steps, where $C$ is a constant indepedent of $x$, and depending only on $M_{w}$ 's alphabet size number of tapes and number of states.

Proof: See section 3.1 in [1], and Th. 1.9 and section 1.7 in [2].

## The Halting Problem

- Consider the following problem: "Given the description of a TM $M$, and a string $x$, will $M$ halt on input $x$ ? " This is called the HALTING PROBLEM.
- We want to compute this problem!!! (Given a computer program and an input, will this program enter an infinite loop?)
- In language form: $\mathrm{H}=\{\llcorner M\lrcorner ; x \mid M(x) \downarrow\}$, where " $\downarrow$ " means that the machine halts, and " $\uparrow$ " that it runs forever.

Theorem
H is recursively enumerable.
Proof: See Th.3.1 (p.59) in [1]

- In fact, H is not just a recursively enumerable language:

If we had an algorithm for deciding $H$, then we would be able to derive an algorithm for deciding any r.e. language (RE-complete).

## The Halting Problem

- But....

Theorem
H is not recursive.

## Proof:

- Suppose, for the sake of contradiction, that there is a TM $M_{H}$ that decides H .
- Consider the TM $D$ :

$$
D(\llcorner M\lrcorner): \text { if } M_{H}(\llcorner M\lrcorner ;\llcorner M\lrcorner)=\text { "yes" then } \uparrow \text { else "yes" }
$$

- What is $D(\llcorner D\lrcorner)$ ?

## The Halting Problem

- But....

Theorem
H is not recursive.

## Proof:

- Suppose, for the sake of contradiction, that there is a TM $M_{H}$ that decides H .
- Consider the TM D:

$$
D(\llcorner M\lrcorner): \text { if } M_{H}(\llcorner M\lrcorner ;\llcorner M\lrcorner)=\text { "yes" then } \uparrow \text { else "yes" }
$$

- What is $D(\llcorner D\lrcorner)$ ?
- If $D(\llcorner D\lrcorner) \uparrow$, then $M_{H}$ accepts the input, so $\llcorner D\lrcorner ;\llcorner D\lrcorner \in H$, so $D(D) \downarrow$.
- If $D(\llcorner D\lrcorner) \downarrow$, then $M_{H}$ rejects $\llcorner D\lrcorner ;\llcorner D\lrcorner$, so $\llcorner D\lrcorner ;\llcorner D\lrcorner \notin \mathrm{H}$, so $D(D) \uparrow . \square$
- Recursive languages are a proper subset of recursive enumerable ones.
- Recall that the complement of a language $L$ is defined as:

$$
\bar{L}=\left\{x \in \Sigma^{*} \mid x \notin L\right\}=\Sigma^{*} \backslash L
$$

## Theorem

(1) If $L$ is recursive, so is $\bar{L}$.

2 $L$ is recursive if and only if $L$ and $\bar{L}$ are recursively enumerable.
Proof: Exercise

- Recursive languages are a proper subset of recursive enumerable ones.
- Recall that the complement of a language $L$ is defined as:

$$
\bar{L}=\left\{x \in \Sigma^{*} \mid x \notin L\right\}=\Sigma^{*} \backslash L
$$

## Theorem

(1) If $L$ is recursive, so is $\bar{L}$.

2 $L$ is recursive if and only if $L$ and $\bar{L}$ are recursively enumerable.
Proof: Exercise

- Let $E(M)=\left\{x \mid\left(q_{0}, \triangleright, \varepsilon\right) \xrightarrow{M *}(q, y \sqcup x \sqcup, \varepsilon\}\right.$
- $E(M)$ is the language enumerated by $M$.

Theorem
$L$ is recursively enumerable iff there is a TM M such that $L=E(M)$.

## More Undecidability

- The HALTING PROBLEM, our first undecidable problem, was the first, but not the only undecidable problem. Its spawns a wide range of such problems, via reductions.
- To show that a problem $A$ is undecidable we establish that, if there is an algorithm for $A$, then there would be an algorithm for H , which is absurd.

Theorem
The following languages are not recursive:
(1) $\{M \mid M$ halts on all inputs $\}$

2 $\{M ; x \mid$ There is a $y$ such that $M(x)=y\}$
${ }^{3}\{M ; x \mid$ The computation of $M$ uses all states of $M\}$
${ }^{4}\{M ; x ; y \mid M(x)=y\}$

## Rice's Theorem

- The previous problems lead us to a more general conlusion:

## Any non-trivial property of Turing Machines is undecidable

- If a TM $M$ accepts a language $L$, we write $L=L(M)$ :

Theorem (Rice's Theorem)
Suppose that $\mathcal{C}$ is a proper, non-empty subset of the set of all recursively enumerable languages. Then, the following problem is undecidable:

Given a Turing Machine $M$, is $L(M) \in \mathcal{C}$ ?

## Rice's Theorem

## Proof:

- We can assume that $\emptyset \notin \mathcal{C}$ (why?).
- Since $\mathcal{C}$ is nonempty, $\exists L \in \mathcal{C}$, accepted by the TM $M_{L}$.
- Let $M_{H}$ the TM deciding the HALTING PROBLEM for an arbitrary input $x$. For each $x \in \Sigma^{*}$, we construct a TM M as follows:
$M(y)$ : if $M_{H}(x)=$ "yes" then $M_{L}(y)$ else $\uparrow$
- We claim that: $L(M) \in \mathcal{C}$ if and only if $x \in H$.

## Rice's Theorem

## Proof:

- We can assume that $\emptyset \notin \mathcal{C}$ (why?).
- Since $\mathcal{C}$ is nonempty, $\exists L \in \mathcal{C}$, accepted by the TM $M_{L}$.
- Let $M_{H}$ the TM deciding the HALTING PROBLEM for an arbitrary input $x$. For each $x \in \Sigma^{*}$, we construct a TM M as follows:
$M(y)$ : if $M_{H}(x)=$ "yes" then $M_{L}(y)$ else $\uparrow$
- We claim that: $L(M) \in \mathcal{C}$ if and only if $x \in H$. Proof of the claim:
- If $x \in H$, then $M_{H}(x)=$ "yes", and so $M$ will accept $y$ or never halt, depending on whether $y \in L$. Then the language accepted by $M$ is exactly $L$, which is in $\mathcal{C}$.
- If $M_{H}(x) \uparrow, M$ never halts, and thus $M$ accepts the language $\emptyset$, which is not in $\mathcal{C}$. $\square$

## Parameters used to define complexity classes:

- Model of Computation (Turing Machine, RAM, Circuits)
- Mode of Computation (Deterministic, Nondeterministic, Probabilistic)
- Complexity Measures (Time, Space, Circuit Size-Depth)
- Other Parameters (Randomization, Interaction)

## Our first complexity classes

## Definition

Let $L \subseteq \Sigma^{*}$, and $T, S: \mathbb{N} \rightarrow \mathbb{N}$ :

- We say that $L \in$ DTIME[T(n)] if there exists a TM M deciding $L$, which operates within the time bound $\mathcal{O}(T(n))$, where $n=|x|$.
- We say that $L \in \operatorname{DSPACE}[S(n)]$ if there exists a TM $M$ deciding $L$, which operates within space bound $\mathcal{O}(S(n))$, that is, for any input $x$, requires space at most $S(|x|)$.
- We say that $L \in$ NTIME[T(n)] if there exists a nondeterministic TM $M$ deciding $L$, which operates within the time bound $\mathcal{O}(T(n))$.
- We say that $L \in \operatorname{NSPACE}[S(n)]$ if there exists a nondeterministic TM M deciding $L$, which operates within space bound $\mathcal{O}(S(n))$.

## Our first complexity classes

- The above are Complexity Classes, in the sense that they are sets of languages.
- All these classes are parameterized by a function $T$ or $S$, so they are families of classes (for each function we obtain a complexity class).

Definition (Complementary complexity class)
For any complexity class $\mathcal{C}$, coC denotes the class: $\{\bar{L} \mid L \in \mathcal{C}\}$, where $\bar{L}=\Sigma^{*} \backslash L=\left\{x \in \Sigma^{*} \mid x \notin L\right\}$.

- We want to define "reasonable" complexity classes, in the sense that we want to "compute more problems", given more computational resources.

## Constructible Functions

- Can we use all computable functions to define Complexity Classes?

Theorem (Gap Theorem)
For any computable functions $r$ and $a$, there exists a computable function $f$ such that $f(n) \geq a(n)$, and
$\operatorname{DTIME}[f(n)]=\operatorname{DTIME}[r(f(n))]$

- That means, for $r(n)=2^{2^{f(n)}}$, the incementation from $f(n)$ to $2^{2^{f(n)}}$ does not allow the computation of any new function!
- So, we must use some restricted families of functions:

## Constructible Functions

## Definition (Time-Constructible Function)

A nondecreasing function $T: \mathbb{N} \rightarrow \mathbb{N}$ is time constructible if $T(n) \geq n$ and there is a TM $M$ that computes the function $x \mapsto\llcorner T(|x|)\lrcorner$ in time $T(n)$.

## Definition (Space-Constructible Function)

A nondecreasing function $S: \mathbb{N} \rightarrow \mathbb{N}$ is space-constructible if $S(n)>\log n$ and there is a TM $M$ that computes $S(|x|)$ using $S(|x|)$ space, given $x$ as input.

- The restriction $T(n) \geq n$ is to allow the machine to read its input.
- The restriction $S(n)>\log n$ is to allow the machine to "remember" the index of the cell of the input tape that it is currently reading.
- Also, if $f_{1}(n), f_{2}(n)$ are time/space-constructible functions, so are $f_{1}+f_{2}, f_{1} \cdot f_{2}$ and $f_{1}^{f_{2}}$.

## Constructible Functions

Theorem (Hierarchy Theorems)
Let $t_{1}, t_{2}$ be time-constructible functions, and $s_{1}, s_{2}$ be space-constructible functions. Then:
(1) If $t_{1}(n) \log t_{1}(n)=o\left(t_{2}(n)\right)$, then $\mathbf{D T I M E}\left(t_{1}\right) \subsetneq \mathbf{D T I M E}\left(t_{2}\right)$.
2) If $t_{1}(n+1)=o\left(t_{2}(n)\right)$, then $\operatorname{NTIME}\left(t_{1}\right) \subsetneq \operatorname{NTIME}\left(t_{2}\right)$.

3 If $s_{1}(n)=o\left(s_{2}(n)\right)$, then $\operatorname{DSPACE}\left(s_{1}\right) \subsetneq \operatorname{DSPACE}\left(s_{2}\right)$.
4. If $s_{1}(n)=o\left(s_{2}(n)\right)$, then $\operatorname{NSPACE}\left(s_{1}\right) \subsetneq \operatorname{NSPACE}\left(s_{2}\right)$.

# Simplified Case of Deterministic Time Hierarchy Theorem 

Theorem
DTIME $[n] \subsetneq$ DTIME $\left[n^{1.5}\right]$

## Simplified Case of Deterministic Time Hierarchy Theorem

## Theorem <br> DTIME $[n] \subsetneq$ DTIME $\left[n^{1.5}\right]$

Proof (Diagonalization):
Let $D$ be the following machine:
On input $x$, run for $|x|^{1.4}$ steps $\mathcal{U}\left(M_{x}, x\right)$; If $\mathcal{U}\left(M_{x}, x\right)=b$, then return $1-b$; Else return 0 ;

- Clearly, $L=L(D) \in$ DTIME $\left[n^{1.5}\right]$
- We claim that $L \notin$ DTIME[n]: Let $L \in$ DTIME $n] \Rightarrow \exists M: M(x)=D(x) \forall x \in \Sigma^{*}$, and $M$ works for $\mathcal{O}(|x|)$ steps.
The time to simulate $M$ using $\mathcal{U}$ is $c|x| \log |x|$, for some $c$.

## Simplified Case of Deterministic Time Hierarchy Theorem

Proof (cont'd):
$\exists n_{0}: n^{1.4}>c n \log n \forall n \geq n_{0}$
There exists a $x_{M}$, s.t. $x_{M}=\llcorner M\lrcorner$ and $\left|x_{M}\right|>n_{0}$ (why?) Then, $D\left(x_{M}\right)=1-M\left(x_{M}\right)$ (while we have also that $\left.D(x)=M(x), \forall x\right)$

## Simplified Case of Deterministic Time Hierarchy Theorem

Proof (cont'd):
$\exists n_{0}: n^{1.4}>c n \log n \forall n \geq n_{0}$
There exists a $x_{M}$, s.t. $x_{M}=\llcorner M\lrcorner$ and $\left|x_{M}\right|>n_{0}$ (why?) Then, $\mathrm{D}\left(\mathrm{x}_{\mathrm{M}}\right)=1-\mathrm{M}\left(\mathrm{x}_{\mathrm{M}}\right)$ (while we have also that $D(x)=M(x), \forall x$ ) Contradiction!!

## Simplified Case of Deterministic Time Hierarchy Theorem

```
Proof (cont'd):
\(\exists n_{0}: n^{1.4}>c n \log n \forall n \geq n_{0}\)
There exists a \(x_{M}\), s.t. \(x_{M}=\llcorner M\lrcorner\) and \(\left|x_{M}\right|>n_{0}\) (why?) Then, \(\mathrm{D}\left(\mathrm{x}_{\mathrm{M}}\right)=1-\mathrm{M}\left(\mathrm{x}_{\mathrm{M}}\right)\) (while we have also that \(\left.D(x)=M(x), \forall x\right)\) Contradiction!!
```

- So, we have the hierachy:

$$
\text { DTIME }[n] \subsetneq \mathrm{D} \operatorname{TIME}\left[n^{2}\right] \subsetneq \mathrm{D} \operatorname{TIME}\left[n^{3}\right] \subsetneq \cdots
$$

- We will later see that the class containing the problems we can efficiently solve (recall the Edmonds-Cobham Thesis) is the class $\mathbf{P}=\bigcup_{c \in \mathbb{N}} \mathbf{D T I M E}\left[n^{c}\right]$.
- Hierarchy Theorems tell us how classes of the same kind relate to each other, when we vary the complexity bound.
- The most interesting results concern relationships between classes of different kinds:

Theorem
Suppose that $T(n), S(n)$ are time-constructible and space-constructible functions, respectively. Then:
(1) DTIME $[T(n)] \subseteq \operatorname{NTIME}[T(n)]$

2 $\operatorname{DSPACE}[S(n)] \subseteq \operatorname{NSPACE}[S(n)]$
3 $\operatorname{NTIME}[T(n)] \subseteq \operatorname{DSPACE}[T(n)]$
4 $\operatorname{NSPACE}[S(n)] \subseteq$ DTIME $\left[2^{\mathcal{O}(S(n))}\right]$
Corollary

$$
\mathrm{NTIME}[T(n)] \subseteq \bigcup_{c>1} \operatorname{DTIME}\left[c^{T(n)}\right]
$$

## Proof:

(1) Trivial
(2) Trivial
3. We can simulate the machine for each nondeterministic choice, using at most $T(n)$ steps in each simulation.
There are exponentially many simulations, but we can simulate them one-by-one, reusing the same space.
4. Recall the notion of a configuration of a TM: For a $k$-tape machine, is a $2 k-2$ tuple: $\left(q, i, w_{2}, u_{2}, \ldots, w_{k-1}, u_{k-1}\right)$ How many configurations are there?

- $|Q|$ choices for the state
- $n+1$ choices for $i$, and
- Fewer than $|\Sigma|^{(2 k-2) S(n)}$ for the remaining strings

So, the total number of configurations on input size $n$ is at most $n c_{1}^{S(n)}=2^{\mathcal{O}(S(n))}$.

Proof (cont'd):
Definition (Configuration Graph of a TM)
The configuration graph of $M$ on input $x$, denoted $G(M, x)$, has as vertices all the possible configurations, and there is an edge between two vertices $C$ and $C^{\prime}$ if and only if $C^{\prime}$ can be reached from $C$ in one step, according to $M$ 's transition function.

- So, we have reduced this simulation to REACHABILITY* problem (also known as S-T CONN), for which we know there is a poly-time $\left(\mathcal{O}\left(n^{2}\right)\right)$ algorithm.
- So, the simulation takes $\left(2^{\mathcal{O}(S(n))}\right)^{2} \sim 2^{\mathcal{O}(S(n))}$ steps.
*REACHABILITY: Given a graph $G$ and two nodes $v_{1}, v_{n} \in V$, is there a path from $v_{1}$ to $v_{n}$ ?

## The essential Complexity Hierarchy

$$

$\mathbf{L} \subseteq \mathbf{N L} \subseteq \mathbf{P} \subseteq \mathbf{N P} \subseteq \mathbf{P S P A C E} \subseteq \mathbf{N P S P A C E} \subseteq \mathbf{E X P} \subseteq \mathbf{N E X P}$

## Certificate Characterization of NP

Definition
Let $R \subseteq \Sigma^{*} \times \Sigma^{*}$ a binary relation on strings.

- $R$ is called polynomially decidable if there is a DTM deciding the language $\{x ; y \mid(x, y) \in R\}$ in polynomial time.
- $R$ is called polynomially balanced if $(x, y) \in R$ implies $|y| \leq|x|^{k}$, for some $k \geq 1$.

Theorem
Let $L \subseteq \Sigma^{*}$ be a language. $L \in \mathbf{N P}$ if and only if there is a polynomially decidable and polynomially balanced relation $R$, such that:

$$
L=\{x \mid \exists y R(x, y)\}
$$

- This $y$ is called succinct certificate, or witness.

## Proof:

$(\Leftarrow)$ If such an $R$ exists, we can construct the following NTM deciding $L$ :
"On input $x$, guess a $y$, such that $|y| \leq|x|^{k}$, and then test (in poly-time) if $(x, y) \in R$. If so, accept, else reject." Observe that an accepting computation exists if and only if $x \in L$.
$(\Rightarrow)$ If $L \in \mathbf{N P}$, then $\exists$ an NTM $N$ that decides $L$ in time $|x|^{k}$, for some $k$. Define the following $R$ :
" $(x, y) \in R$ if and only if $y$ is an encoding of an accepting computation of $N(x)$."
$R$ is polynomially balanced and decidable (why?), so, given by assumption that $N$ decides $L$, we have our conclusion.

## Can creativity be automated?

As we saw:

- Class P: Efficient Computation
- Class NP: Efficient Verification
- So, if we can efficiently verify a mathematical proof, can we create it efficiently?

If $P=N P$...

- For every mathematical statement, and given a page limit, we would (quickly) generate a proof, if one exists.
- Given detailed constraints on an engineering task, we would (quickly) generate a design which meets the given criteria, if one exists.
- Given data on some phenomenon and modeling restrictions, we would (quickly) generate a theory to explain the data, if one exists.

## Complementary complexity classes

- Deterministic complexity classes are in general closed under complement (coL = $\mathbf{L}, c o \mathbf{P}=\mathbf{P}, \operatorname{coPSPACE}=\mathbf{P S P A C E}$ ).
- Complementaries of non-deterministic complexity classes are very interesting:
- The class coNP contains all the languages that have succinct disqualifications (the analogue of succinct certificate for the class NP). The "no" instance of a problem in coNP has a short proof of its being a "no" instance.
- So:

- Note the similarity and the difference with $\mathbf{R}=\mathbf{R E} \cap$ coRE.

## Certificates \& Quantifiers

## Quantifier Characterization of Complexity Classes

## Definition

We denote as $\mathcal{C}=\left(Q_{1} / Q_{2}\right)$, where $Q_{1}, Q_{2} \in\{\exists, \forall\}$, the class $\mathcal{C}$ of languages $L$ satisfying:

- $x \in L \Rightarrow Q_{1} y R(x, y)$
- $x \notin L \Rightarrow Q_{2} y \neg R(x, y)$
- $\mathbf{P}=(\forall / \forall)$
- NP $=(\exists / \forall)$
- coNP $=(\forall / \exists)$

## Savitch's Theorem

- REACHABILITY $\in$ NL.

Theorem (Savitch's Theorem) REACHABILITY $\in$ DSPACE $\left[\log ^{2} n\right]$

Proof:
See Th. 7.4 (p.149) in [1]
$\operatorname{REACH}(x, y, i):$ "There is a path from $x$ to $y$, of length $\leq i$ ".

- We can solve REACHABILITY if we can compute $\operatorname{REACH}(x, y, n)$, for any nodes $x, y \in V$, since any path in $G$ can be at most $n$ long.
- If $i=1$, we can check whether $\operatorname{REACH}(x, y, i)$.
- If $i>1$, we use recursion:

```
def REACH(s,t,k)
    if k==1:
        if (s==t or (s,t) in edges): return true
    if k>1:
        for u in vertices:
            if (REACH(s,u, floor(k/2)) and
                            (REACH(u,t,ceil(k/2)))): return true
    return false
```

```
def REACH(s,t,k)
    if k==1:
        if (s==t or (s,t) in edges): return true
    if k>1:
        for u in vertices:
            if (REACH(s,u, floor(k/2)) and
                            (REACH(u,t,ceil(k/2)))): return true
        return false
```

- We generate all nodes $u$ one after the other, reusing space.
- The algorithm has recursion depth of $\lceil\log n\rceil$.
- For each recursion level, we have to store $s, t, k$ and $u$, that is, $\mathcal{O}(\log n)$ space.
- Thus, the total space used is $\mathcal{O}\left(\log ^{2} n\right)$. $\square$

## Savitch's Theorem

Corollary
$\operatorname{NSPACE}[S(n)] \subseteq \operatorname{DSPACE}\left[S^{2}(n)\right]$, for any space-constructible function $S(n) \geq \log n$.

## Proof:

- Let $M$ be the nondeterministic TM to be simulated.
- We run the algorithm of Savitch's Theorem proof on the configuration graph of $M$ on input $x$.
- Since the configuration graph has $c^{S(n)}$ nodes, $\mathcal{O}\left(S^{2}(n)\right)$ space suffices. $\qquad$

Corollary

## PSPACE = NPSPACE

## NL-Completeness

- In Complexity Theory, we "connect" problems in a complexity class with partial ordering relations, called reductions, which formalize the notion of "a problem that is at least as hard as another".
- A reduction must be computationally weaker than the class in which we use it.

Definition
A language $L_{1}$ is logspace reducible to a language $L_{2}$, denoted $L_{1} \leq_{m}^{\ell} L_{2}$, if there is a function $f: \Sigma^{*} \rightarrow \Sigma^{*}$, computable by a DTM in $\mathcal{O}(\log n)$ space, such that for all $x \in \Sigma^{*}$ :

$$
x \in L_{1} \Leftrightarrow f(x) \in L_{2}
$$

We say that a language $A$ is NL-complete if it is in NL and for every $B \in \mathbf{N L}, B \leq_{m}^{\ell} A$.

## NL-Completeness

## Theorem <br> REACHABILITY is NL-complete.

## NL-Completeness

## Theorem <br> REACHABILITY is NL-complete.

Proof:

- We 've argued why REACHABILITY $\in$ NL.
- Let $L \in \mathbf{N L}$, that is, it is decided by a $\mathcal{O}(\log n)$ NTM $N$.
- Given input $x$, we can construct the configuration graph of $N(x)$.
- We can assume that this graph has a single accepting node.
- We can construct this in logspace: Given configurations $C, C^{\prime}$ we can in space $\mathcal{O}\left(|C|+\left|C^{\prime}\right|\right)=\mathcal{O}(\log |x|)$ check the graph's adjacency matrix if they are connected by an edge.
- It is clear that $x \in L$ if and only if the produced instance of REACHABILITY has a "yes" answer. $\square$

## Certificate Definition of NL

- We want to give a characterization of NL, similar to the one we gave for NP.
- A certificate may be polynomially long, so a logspace machine may not have the space to store it.
- So, we will assume that the certificate is provided to the machine on a separate tape that is read once.

## Certificate Definition of NL

Definition
A language $L$ is in NL if there exists a deterministic TM $M$ with an additional special read-once input tape, such that for every $x \in \Sigma^{*}$ :

$$
x \in L \Leftrightarrow \exists y,|y| \in \operatorname{poly}(|x|), M(x, y)=1
$$

where by $M(x, y)$ we denote the output of $M$ where $x$ is placed on its input tape, and $y$ is placed on its special read-once tape, and $M$ uses at most $\mathcal{O}(\log |x|)$ space on its read-write tapes for every input $x$.

- What if remove the read-once restriction and allow the TM's head to move back and forth on the certificate, and read each bit multiple times?

## Immerman-Szelepscényi

Theorem (The Immerman-Szelepscényi Theorem)
$\overline{\text { REACHABILITY }} \in$ NL

## Immerman-Szelepscényi

## Theorem (The Immerman-Szelepscényi Theorem)

## $\overline{\text { REACHABILITY }} \in \mathrm{NL}$

Proof:

- It suffices to show a $\mathcal{O}(\log n)$ verification algorithm $A$ such that: $\forall(G, s, t), \exists$ a polynomial certificate $u$ such that: $A((G, s, t), u)=$ "yes" iff $t$ is not reachable from $s$.
- A has read-once access to $u$.
- G's vertices are identified by numbers in $\{1, \ldots, n\}=[n]$
- $C_{i}$ : "The set of vertices reachable from $s$ in $\leq i$ steps."
- Membership in $C_{i}$ is easily certified:
- $\forall i \in[n]: v_{0}, \ldots, v_{k}$ along the path from $s$ to $v, k \leq i$.
- The certificate is at most polynomial in $n$.

## The Immerman-Szelepscényi Theorem

## Proof (cont'd):

- We can check the certificate using read-once access:
(1) $v_{0}=s$
(2) for $j>0,\left(v_{j-1}, v_{j}\right) \in E(G)$
(3) $v_{k}=v$

4 Path ends within at most $i$ steps

- We now construct two types of certificates:
(1) A certificate that a vertex $v \notin C_{i}$, given $\left|C_{i}\right|$.

2) A certificate that $\left|C_{i}\right|=c$, for some $c$, given $\left|C_{i-1}\right|$.

- Since $C_{0}=\{s\}$, we can provide the 2 nd certificate to convince the verifier for the sizes of $C_{1}, \ldots, C_{n}$
- $C_{n}$ is the set of vertices reachable from $s$.

## The Immerman-Szelepscényi Theorem

Proof (cont'd):

- Since the verifier has been convinced of $\left|C_{n}\right|$, we can use the 1st type of certificate to convince the verifier that $t \notin C_{n}$.
- Certifying that $v \notin C_{i}$, given $\left|C_{i}\right|$

The certificate is the list of certificates that $u \in C_{i}$, for every $u \in C_{i}$.
The verifier will check:
(1) Each certificate is valid
(2) Vertex $u$, given a certificate for $u$, is larger than the previous.

3 No certificate is provided for $v$.
4 The total number of certificates is exactly $\left|C_{i}\right|$.

## The Immerman-Szelepscényi Theorem

Proof (cont'd):
Certifying that $v \notin C_{i}$, given $\left|C_{i-1}\right|$
The certificate is the list of certificates that $u \in C_{i-1}$, for every $u \in C_{i-1}$
The verifier will check:

1) Each certificate is valid
(2) Vertex $u$, given a certificate for $u$, is larger than the previous.
${ }^{3}$ No certificate is provided for $v$ or for a neighbour of $v$.
4 The total number of certificates is exactly $\left|C_{i-1}\right|$.
Certifying that $\left|C_{i}\right|=c$, given $\left|C_{i-1}\right|$
The certificate will consist of $n$ certificates, for vertices 1 to $n$, in ascending order.
The verifier will check all certificates, and count the vertices that have been certified to be in $C_{i}$. If $\left|C_{i}\right|=c$, it accepts. $\square$

## The Immerman-Szelepscényi Theorem

Corollary
For every space constructible $S(n)>\log n$ :

## $\operatorname{NSPACE}[S(n)]=\operatorname{coNSPACE}[S(n)]$

## Proof:

- Let $L \in \operatorname{NSPACE}[S(n)]$. We will show that $\exists S(n)$ space-bounded NTM $\bar{M}$ deciding $\bar{L}$ :
- $\bar{M}$ on input $x$ uses the above certification procedure on the configuration graph of $M$. $\square$

Corollary

$$
\mathrm{NL}=c o \mathrm{NL}
$$

## What about Undirected Reachability?

- UNDIRECTED REACHABILITY captures the phenomenon of configuration graphs with both directions.
- H. Lewis and C. Papadimitriou defined the class SL (Symmetric Logspace) as the class of languages decided by a Symmetric Turing Machine using logarithmic space.
- Obviously,

## $\mathbf{L} \subseteq \mathbf{S L} \subseteq \mathbf{N L}$

- As in the case of NL, UNDIRECTED REACHABILITY is SL-complete.
- But in 2004, Omer Reingold showed, using expander graphs, a deterministic logspace algorithm for UNDIRECTED REACHABILITY, so:

Theorem (Reingold, 2004)

$$
\mathbf{L}=\mathbf{S L}
$$

## Our Complexity Hierarchy Landscape

## Karp Reductions

Definition
A language $L_{1}$ is Karp reducible to a language $L_{2}$, denoted by $L_{1} \leq_{m}^{p} L_{2}$, if there is a function $f: \Sigma^{*} \rightarrow \Sigma^{*}$, computable by a polynomial-time DTM, such that for all $x \in \Sigma^{*}$ :

$$
x \in L_{1} \Leftrightarrow f(x) \in L_{2}
$$

## Karp Reductions

Definition
A language $L_{1}$ is Karp reducible to a language $L_{2}$, denoted by $L_{1} \leq_{m}^{p} L_{2}$, if there is a function $f: \Sigma^{*} \rightarrow \Sigma^{*}$, computable by a polynomial-time DTM, such that for all $x \in \Sigma^{*}$ :

$$
x \in L_{1} \Leftrightarrow f(x) \in L_{2}
$$

Definition
Let $\mathcal{C}$ be a complexity class.

- We say that a language $A$ is $C$-hard (or $\leq_{m}^{p}$-hard for $\mathcal{C}$ ) if for every $B \in \mathcal{C}, B \leq_{m}^{p} A$.
- We say that a language $A$ is $C$-complete, if it is $\mathcal{C}$-hard, and also $A \in \mathcal{C}$.

## Karp reductions vs logspace redutions

Theorem
A logspace reduction is a polynomial-time reduction.

## Proof:

- Let $M$ the logspace reduction TM.
- $M$ has $2^{\mathcal{O}(\log n)}$ possible configurations.
- The machine is deterministic, so no configuration can be repeated in the computation.
- So, the computation takes $\mathcal{O}\left(n^{k}\right)$ time, for some $k$.

## Circuits and CVP

## Definition (Boolean circuits)

For every $n \in \mathbb{N}$ an $n$-input, single output Boolean Circuit $C$ is a directed acyclic graph with $n$ sources and one sink.

- All nonsource vertices are called gates and are labeled with one of $\wedge$ (and), $\vee$ (or) or $\neg$ (not).
- The vertices labeled with $\wedge$ and $\vee$ have fan-in (i.e. number or incoming edges) 2.
- The vertices labeled with $\neg$ have fan-in 1 .
- For every vertex $v$ of $C$, we assign a value as follows: for some input $x \in\{0,1\}^{n}$, if $v$ is the $i$-th input vertex then $\operatorname{val}(v)=x_{i}$, and otherwise $v a l(v)$ is defined recursively by applying $v$ 's logical operation on the values of the vertices connected to $v$.
- The output $C(x)$ is the value of the output vertex.

## Circuits and CVP

## Definition (CVP)

Circuit Value Problem (CVP): Given a circuit $C$ and an assignment $x$ to its variables, determine whether $C(x)=1$.

- $\mathrm{CVP} \in \mathbf{P}$.

## Circuits and CVP

Definition (CVP)
Circuit Value Problem (CVP): Given a circuit $C$ and an assignment $x$ to its variables, determine whether $C(x)=1$.

- $\mathrm{CVP} \in \mathbf{P}$.

## Example

REACHABILITY $\leq_{m}^{\ell}$ CVP: Graph $G \rightarrow$ circuit $R(G)$ :

- The gates are of the form:
- $g_{i, j, k}, 1 \leq i, j \leq n, 0 \leq k \leq n$.
- $h_{i, j, k}, 1 \leq i, j, k \leq n$
- $g_{i, j, k}$ is true iff there is a path from $i$ to $j$ without intermediate nodes bigger than $k$.
- $h_{i, j, k}$ is true iff there is a path from $i$ to $j$ without intermediate nodes bigger than $k$, and $k$ is used.

## Circuits and CVP

## Example

- Input gates: $g_{i, j, 0}$ is true iff $(i=j$ or $(i, j) \in E(G))$.
- For $k=1, \ldots, n: h_{i, j, k}=\left(g_{i, k, k-1} \wedge g_{k, j, k-1}\right)$
- For $k=1, \ldots, n: g_{i, j, k}=\left(g_{i, j, k-1} \vee h_{i, j, k}\right)$
- The output gate $g_{1, n, n}$ is true iff there is a path from 1 to $n$ using no intermediate paths above $n$ (sic).
- We also can compute the reduction in logspace: go over all possible $i, j, k$ 's and output the appropriate edges and sorts for the variables $\left(1, \ldots, 2 n^{3}+n^{2}\right)$.

## Composing Reductions

Theorem
If $L_{1} \leq_{m}^{\ell} L_{2}$ and $L_{2} \leq_{m}^{\ell} L_{3}$, then $L_{1} \leq_{m}^{\ell} L_{3}$.
Proof:

- Let $R, R^{\prime}$ be the aforementioned reductions.
- We have to prove that $R^{\prime}(R(x))$ is a logspace reduction.
- But $R(x)$ may by longer than $\log |x| \ldots$
- We simulate $M_{R^{\prime}}$ by remembering the head position $i$ of the input string of $M_{R^{\prime}}$, i.e. the output string of $M_{R}$.
- If the head moves to the right, we increment $i$ and simulate $M_{R}$ long enough to take the $i^{\text {th }}$ bit of the output.
- If the head stays in the same position, we just remember the $i^{\text {th }}$ bit.
- If the head moves to the left, we decrement $i$ and start $M_{R}$ from the beggining, until we reach the desired bit.

## Closure under reductions

- Complete problems are the maximal elements of the reductions partial ordering.
- Complete problems capture the essence and difficulty of a complexity class.

Definition
A class $\mathcal{C}$ is closed under reductions if for all $A, B \subseteq \Sigma^{*}$ :
If $A \leq B$ and $B \in \mathcal{C}$, then $A \in \mathcal{C}$.

- P, NP, coNP, L, NL, PSPACE, EXP are closed under Karp and logspace reductions.
- If an NP-complete language is in $\mathbf{P}$, then $\mathbf{P}=\mathbf{N P}$.
- If $L$ is NP-complete, then $\bar{L}$ is coNP-complete.
- If a coNP-complete problem is in NP, then NP $=$ coNP.

## P-Completeness

## Theorem

If two classes $\mathcal{C}$ and $\mathcal{C}^{\prime}$ are both closed under reductions and there is an $L \subseteq \Sigma^{*}$ complete for both $\mathcal{C}$ and $\mathcal{C}^{\prime}$, then $\mathcal{C}=\mathcal{C}^{\prime}$.

- Consider the Computation Table $T$ of a poly-time TM $M(x)$ :
$T_{i j}$ represents the contents of tape position $j$ at step $i$.
- But how to remember the head position and state? At the $i^{\text {th }}$ step: if the state is $q$ and the head is in position $j$, then $T_{i j} \in \Sigma \times Q$.
- We say that the table is accepting if $T_{|x|^{k}-1, j} \in\left(\Sigma \times\left\{q_{y e s}\right\}\right)$, for some $j$.
- Observe that $T_{i j}$ depends only on the contents of the same of adjacent positions at time $i-1$.

## P-Completeness

Theorem
CVP is $\mathbf{P}$-complete.

## P-Completeness

Theorem
CVP is $\mathbf{P}$-complete.

## Proof:

- We have to show that for any $L \in \mathbf{P}$ there is a reduction $R$ from $L$ to CVP.
- $R(x)$ must be a variable-free circuit such that $x \in L \Leftrightarrow R(x)=1$.
- $T_{i j}$ depends only on $T_{i-1, j-1}, T_{i-1, j}, T_{i-1, j+1}$.
- Let $\Gamma=\Sigma \cup(\Sigma \times Q)$.
- Encode $s \in \Gamma$ as $\left(s_{1}, \ldots, s_{m}\right)$, where $m=\lceil\log |\Gamma|\rceil$.
- Then the computation table can be seen as a table of binary entries $S_{i j \ell}, 1 \leq \ell \leq m$.
- $S_{i j \ell}$ depends only on the $3 m$ entries $S_{i-1, j-1, \ell^{\prime}}, S_{i-1, j, \ell^{\prime}}, S_{i-1, j+1, \ell^{\prime}}$, where $1 \leq \ell^{\prime} \leq m$.

## P-Completeness

Proof (cont'd):

- So, there are $m$ Boolean Functions

$$
\begin{aligned}
& f_{1}, \ldots, f_{m}:\{0,1\}^{3 m} \rightarrow\{0,1\} \text { s.t.: } \\
& \qquad S_{i j \ell}=f_{\ell}\left(\vec{S}_{i-1, j-1}, \vec{S}_{i-1, j}, \vec{S}_{i-1, j+1}\right)
\end{aligned}
$$

- Thus, there exists a Boolean Circuit $C$ with $3 m$ inputs and $m$ outputs computing $T_{i j}$.
- C depends only on $M$, and has constant size.
- $R(x)$ will be $\left(|x|^{k}-1\right) \times\left(|x|^{k}-2\right)$ copies of $C$.
- The input gates are fixed.
- $R(x)$ 's output gate will be the first bit of $C_{|x|^{k}-1,1}$.
- The circuit $C$ is fixed, so we can generate indexed copies of $C$, using $\mathcal{O}(\log |x|)$ space for indexing.

## CIRCUIT SAT \& SAT

Definition (CIRCUIT SAT)
Given Boolen Circuit $C$, is there a truth assignment $x$ appropriate to $C$, such that $C(x)=1$ ?

Definition (SAT)
Given a Boolean Expression $\phi$ in CNF, is it satisfiable?

## CIRCUIT SAT \& SAT

Definition (CIRCUIT SAT)
Given Boolen Circuit $C$, is there a truth assignment $x$ appropriate to $C$, such that $C(x)=1$ ?

Definition (SAT)
Given a Boolean Expression $\phi$ in CNF, is it satisfiable?

## Example

CIRCUIT SAT $\leq_{m}^{\ell}$ SAT:

- Given $C \rightarrow$ Boolean Formula $R(C)$, s.t.

$$
C(x)=1 \Leftrightarrow R(C)(x)=T .
$$

- Variables of $C \rightarrow$ variables of $R(C)$.
- Gate $g$ of $C \rightarrow$ variable $g$ of $R(C)$.

## CIRCUIT SAT \& SAT

## Example

- Gate $g$ of $C \rightarrow$ clauses in $R(C)$ :
- $g$ variable gate: add $(\neg g \vee x) \wedge(g \vee \neg x)$

$$
\equiv g \Leftrightarrow x
$$

- g TRUE gate: add (g)
- $g$ FALSE gate: add ( $\neg g$ )
- $g$ NOT gate \& $\operatorname{pred}(g)=h$ : add $(\neg g \vee \neg h) \wedge(g \vee h)$
- $g$ OR gate \& $\operatorname{pred}(g)=\left\{h, h^{\prime}\right\}:$ add $(\neg h \vee g) \wedge\left(\neg h^{\prime} \vee g\right) \wedge\left(h \vee h^{\prime} \vee \neg g\right)$
$\equiv g \Leftrightarrow\left(h \vee h^{\prime}\right)$
- $g$ AND gate \& $\operatorname{pred}(g)=\left\{h, h^{\prime}\right\}$ : add $(\neg g \vee h) \wedge\left(\neg g \vee h^{\prime}\right) \wedge\left(\neg h \vee \neg h^{\prime} \vee g\right)$
$\equiv g \Leftrightarrow\left(h \wedge h^{\prime}\right)$
- $g$ output gate: add ( $g$ )
- $R(C)$ is satisfiable if and only if $C$ is.
- The construction can be done within $\log |x|$ space.

## Bounded Halting Problem

- We can define the time-bounded analogue of HP:

Definition (Bounded Halting Problem (BHP))
Given the code $\llcorner M\lrcorner$ of an NTM $M$, and input $x$ and a string $0^{t}$, decide if $M$ accepts $x$ in $t$ steps.

Theorem BHP is NP-complete.

## Proof:

- BHP $\in \mathbf{N P}$.
- Let $A \in$ NP. Then, $\exists$ NTM $M$ deciding $A$ in time $p(|x|)$, for some $p \in \operatorname{poly}(|x|)$.
- The reduction is the function $R(x)=\left\langle\llcorner M\lrcorner, x, 0^{p(|x|)}\right\rangle$.

## Cook's Theorem

Theorem (Cook's Theorem)
SAT is NP-complete.

## Cook's Theorem

Theorem (Cook's Theorem)
SAT is NP-complete.

Proof:

- $\operatorname{SAT} \in \mathbf{N P}$.
- Let $L \in$ NP. We will show that $L \leq_{m}^{\ell}$ CIRCUIT SAT $\leq_{m}^{\ell}$ SAT.
- Since $L \in$ NP, there exists an NPTM $M$ deciding $L$ in $n^{k}$ steps.
- Let $\left(c_{1}, \ldots, c_{n^{k}}\right) \in\{0,1\}^{n^{k}}$ a certificate for $M$ (recall the binary encoding of the computation tree).

## Cook's Theorem

Proof (cont'd):

- If we fix a certificate, then the computation is deterministic (the language's Verifier $V(x, y)$ is a DPTM).
- So, we can define the computation table $T(M, x, \vec{c})$.
- As before, all non-top row and non-extreme column cells $T_{i j}$ will depend only on $T_{i-1, j-1}, T_{i-1, j}, T_{i-1, j+1}$ and the nondeterministic choice $c_{i-1}$.
- We now fixed a circuit $C$ with $3 m+1$ input gates.
- Thus, we can construct in $\log |x|$ space a circuit $R(x)$ with variable gates $c_{1}, \ldots c_{n^{k}}$ corresponding to the nondeterministic choices of the machine.
- $R(x)$ is satisfiable if and only if $x \in L$.

## NP-completeness: Web of Reductions

- Many NP-complete problems stem from Cook's Theorem via reductions:
- 3SAT, MAX2SAT, NAESAT
- IS, CLIQUE, VERTEX COVER, MAX CUT
- TSP $(\mathrm{D}), 3 \mathrm{COL}$
- SET COVER, PARTITION, KNAPSACK, BIN PACKING
- INTEGER PROGRAMMING (IP): Given $m$ inequalities oven $n$ variables $u_{i} \in\{0,1\}$, is there an assignment satisfying all the inequalities?
- Always remember that these are decision versions of the corresponding optimization problems.
- But 2 SAT, $2 \mathrm{COL} \in \mathbf{P}$.

## NP-completeness: Web of Reductions

## Example

$\mathrm{SAT} \leq_{m}^{\ell}$ IP:

- Every clause can be expressed as an inequality, eg:

$$
\left(x_{1} \vee \bar{x}_{2} \vee \bar{x}_{3}\right) \longrightarrow x_{1}+\left(1-x_{2}\right)+\left(1-x_{3}\right) \geq 1
$$

## NP-completeness: Web of Reductions

Example
SAT $\leq_{m}^{\ell} \mathrm{IP}$ :

- Every clause can be expressed as an inequality, eg:

$$
\left(x_{1} \vee \bar{x}_{2} \vee \bar{x}_{3}\right) \longrightarrow x_{1}+\left(1-x_{2}\right)+\left(1-x_{3}\right) \geq 1
$$

- This method is generalized by the notion of Constraint Satisfaction Problems.
- A Constraint Satisfaction Problem (CSP) generalizes SAT by allowing clauses of arbitrary form (instead of ORs of literals).

3SAT is the subcase of $q C S P$, where arity $q=3$ and the constraints are ORs of the involved literals.

## Quantified Boolean Formulas

Definition (Quantified Boolean Formula)
A Quantified Boolean Formula $F$ is a formula of the form:

$$
F=\exists x_{1} \forall x_{2} \exists x_{3} \cdots Q_{n} x_{n} \phi\left(x_{1}, \ldots, x_{n}\right)
$$

where $\phi$ is plain (quantifier-free) boolean formula.

- Let TQBF the language of all true QBFs.

## Quantified Boolean Formulas

Definition (Quantified Boolean Formula)
A Quantified Boolean Formula $F$ is a formula of the form:

$$
F=\exists x_{1} \forall x_{2} \exists x_{3} \cdots Q_{n} x_{n} \phi\left(x_{1}, \ldots, x_{n}\right)
$$

where $\phi$ is plain (quantifier-free) boolean formula.

- Let TQBF the language of all true QBFs.

## Example

$$
F=\exists x_{1} \forall x_{2} \exists x_{3}\left[\left(x_{1} \vee \neg x_{2}\right) \wedge\left(\neg x_{2} \vee x_{3}\right) \wedge\left(\neg x_{1} \vee x_{2} \vee \neg x_{3}\right)\right]
$$

The above is a True QBF $((1,0,0)$ and $(1,1,1)$ satisfy it).

# Quantified Boolean Formulas 

## Theorem <br> TQBF is PSPACE-complete.

## Quantified Boolean Formulas

Theorem<br>TQBF is PSPACE-complete.

## Proof:

See Th. 19.1 (p.456) in [1] - Th. 4.13 (p.84) in [2]

- TQBF $\in$ PSPACE:
- Let $\phi$ be a QBF, with $n$ variables and length $m$.
- Recursive algorithm $A(\phi)$ :
- If $n=0$, then there are only constants, hence $\mathcal{O}(m)$ time/space.
- If $n>0$ :

$$
\begin{aligned}
& A(\phi)=A\left(\left.\phi\right|_{x_{1}=0}\right) \vee A\left(\left.\phi\right|_{x_{1}=1}\right), \text { if } Q_{1}=\exists \text {, and } \\
& A(\phi)=A\left(\left.\phi\right|_{x_{1}=0}\right) \wedge A\left(\left.\phi\right|_{x_{1}=1}\right) \text {, if } Q_{1}=\forall .
\end{aligned}
$$

- Both recursive computations can be run on the same space.
- So space $_{n, m}=$ space $_{n-1, m}+\mathcal{O}(m) \Rightarrow$ space $_{n, m}=\mathcal{O}(n \cdot m)$.

## Quantified Boolean Formulas

Proof (cont'd):

- Now, let $M$ a TM with space bound $p(n)$.
- We can create the configuration graph of $M(x)$, having size $2^{\mathcal{O}(p(n))}$.
- $M$ accepts $x$ iff there is a path of length at most $2^{\mathcal{O}(p(n))}$ from the initial to the accepting configuration.
- Using Savitch's Theorem idea, for two configurations $C$ and $C^{\prime}$ we have: $\operatorname{REACH}\left(C, C^{\prime}, 2^{i}\right) \Leftrightarrow$
$\Leftrightarrow \exists C^{\prime \prime}\left[R E A C H\left(C, C^{\prime \prime}, 2^{i-1}\right) \wedge R E A C H\left(C^{\prime \prime}, C^{\prime}, 2^{i-1}\right)\right]$

## Quantified Boolean Formulas

Proof (cont'd):

- Now, let $M$ a TM with space bound $p(n)$.
- We can create the configuration graph of $M(x)$, having size $2^{\mathcal{O}(p(n))}$.
- $M$ accepts $x$ iff there is a path of length at most $2^{\mathcal{O}(p(n))}$ from the initial to the accepting configuration.
- Using Savitch's Theorem idea, for two configurations $C$ and $C^{\prime}$ we have: $\operatorname{REACH}\left(C, C^{\prime}, 2^{i}\right) \Leftrightarrow$ $\Leftrightarrow \exists C^{\prime \prime}\left[R E A C H\left(C, C^{\prime \prime}, 2^{i-1}\right) \wedge R E A C H\left(C^{\prime \prime}, C^{\prime}, 2^{i-1}\right)\right]$
- But, this is a bad idea: Doubles the size each time.
- Instead, we use additional variables: $\exists C^{\prime \prime} \forall D_{1} \forall D_{2}\left[\left(D_{1}=C \wedge D_{2}=C^{\prime \prime}\right) \vee\left(D_{1}=C^{\prime \prime} \wedge D_{2}=C^{\prime}\right)\right] \Rightarrow$ $\operatorname{REACH}\left(D_{1}, D_{2}, 2^{i-1}\right)$

## Quantified Boolean Formulas

Proof (cont'd):

- The base case of the recursion is $C_{1} \rightarrow C_{2}$, and can be encoded as a quantifier-free formula.
- The size of the formula in the $i^{\text {th }}$ step is

$$
s_{i} \leq s_{i-1}+\mathcal{O}(p(n)) \Rightarrow \mathcal{O}\left(p^{2}(n)\right)
$$

## *Logical Characterizations

- Descriptive complexity is a branch of computational complexity theory and of finite model theory that characterizes complexity classes by the type of logic needed to express the languages in them.

Theorem (Fagin's Theorem)
The set of all properties expressible in Existential Second-Order Logic is precisely NP.

Theorem
The class of all properties expressible in Horn Existential Second-Order Logic with Successor is precisely $\mathbf{P}$.

- HORNSAT is P-complete.

## Oracle TMs and Oracle Classes

Definition
A Turing Machine $M$ ? with oracle is a multi-string deterministic TM that has a special string, called query string, and three special states: $q_{\text {? }}$ (query state), and $q_{Y E S}, q_{N O}$ (answer states). Let $A \subseteq \Sigma^{*}$ be an arbitrary language. The computation of oracle machine $M^{A}$ proceeds like an ordinary TM except for transitions from the query state: From the $q_{\text {? }}$ moves to either $q_{Y E S}, q_{N O}$, depending on whether the current query string is in $A$ or not.

- The answer states allow the machine to use this answer to its further computation.
- The computation of $M$ ? with oracle $A$ on iput $x$ is denoted as $M^{A}(x)$.

## Oracle TMs and Oracle Classes

## Definition

Let $\mathcal{C}$ be a time complexity class (deterministic or nondeterministic).
Define $\mathcal{C}^{A}$ to be the class of all languages decided by machines of the same sort and time bound as in $\mathcal{C}$, only that the machines have now oracle access to $A$. Also, we define: $\mathcal{C}_{1}^{\mathcal{C}_{2}}=\bigcup_{L \in \mathcal{C}_{2}} \mathcal{C}_{1}^{L}$.

For example, $\mathbf{P}^{N P}=\bigcup_{L \in N P} \mathbf{P}^{L}$. Note that $\mathbf{P}^{\text {SAT }}=\mathbf{P}^{N P}$.
Theorem
There exists an oracle $A$ for which $\mathbf{P}^{A}=\mathbf{N P}^{A}$.

## Proof:

Th.14.4, p. 340 in [1]
Take $A$ to be a PSPACE-complete language. Then:
$\mathbf{P S P A C E} \subseteq \mathbf{P}^{A} \subseteq \mathbf{N P}^{A} \subseteq \mathbf{P S P A C E}^{A} \subseteq$ PSPACE.$\square$

## Oracle TMs and Oracle Classes

## Theorem

There exists an oracle $B$ for which $\mathbf{P}^{B} \neq \mathbf{N P}^{B}$.
Proof:

- We will find a language $L \in \mathbf{N P}^{B} \backslash \mathbf{P}^{B}$.
- Let $L=\left\{1^{n} \mid \exists x \in B\right.$ with $\left.|x|=n\right\}$.
- $L \in \mathbf{N P}^{B}$ (why?)
- We will define the oracle $B \subseteq\{0,1\}^{*}$ such that $L \notin \mathbf{P}^{B}$ :

## Oracle TMs and Oracle Classes

## Theorem

There exists an oracle $B$ for which $\mathbf{P}^{B} \neq \mathbf{N P}^{B}$.
Proof:

- We will find a language $L \in \mathbf{N P}^{B} \backslash \mathbf{P}^{B}$.
- Let $L=\left\{1^{n} \mid \exists x \in B\right.$ with $\left.|x|=n\right\}$.
- $L \in \mathbf{N P}^{B}$ (why?)
- We will define the oracle $B \subseteq\{0,1\}^{*}$ such that $L \notin \mathbf{P}^{B}$ :
- Let $M_{1}^{?}, M_{2}^{?}, \ldots$ an enumeration of all PDTMs with oracle, such that every machine appears infinitely many times in the enumeration.
- We will define $B$ iteratively: $B_{0}=\emptyset$, and $B=\bigcup_{i \geq 0} B_{i}$.
- In $i^{\text {th }}$ stage, we have defined $B_{i-1}$, the set of all strings in $B$ with length $<i$.
- Let also $X$ the set of exceptions.

## Proof (cont'd):

- We simulate $M_{i}^{B}\left(1^{i}\right)$ for $i^{\log i}$ steps.
- How do we answer the oracle questions "Is $x \in B$ "?

## Proof (cont'd):

- We simulate $M_{i}^{B}\left(1^{i}\right)$ for $i^{\log i}$ steps.
- How do we answer the oracle questions "Is $x \in B$ "?
- If $|x|<i$, we look for $x$ in $B_{i-1}$.
- $\rightarrow$ If $x \in B_{i-1}, M_{i}^{B}$ goes to qYES
$\rightarrow$ Else $M_{i}^{B}$ goes to $q_{N O}$
- If $|x| \geq i, M_{i}^{B}$ goes to $q_{N O}$, and $x \rightarrow X$.

Proof (cont'd):

- We simulate $M_{i}^{B}\left(1^{i}\right)$ for $i^{\log i}$ steps.
- How do we answer the oracle questions " $\mid s x \in B$ "?
- If $|x|<i$, we look for $x$ in $B_{i-1}$.
- $\rightarrow$ If $x \in B_{i-1}, M_{i}^{B}$ goes to $q_{Y E S}$
$\rightarrow$ Else $M_{i}^{B}$ goes to $q_{N O}$
- If $|x| \geq i, M_{i}^{B}$ goes to $q_{N O}$, and $x \rightarrow X$.
- Suppose that after at most $i^{\log i}$ steps the machine rejects.
- Then we define $B_{i}=B_{i-1} \cup\left\{x \in\{0,1\}^{*}:|x|=i, x \notin X\right\}$ so $1^{i} \in L$, and $L\left(M_{i}^{B}\right) \neq L$.
-Why $\left\{x \in\{0,1\}^{*}:|x|=i, x \notin X\right\} \neq \emptyset$ ? ?
- If the machine accepts, we define $B_{i}=B_{i-1}$, so that $1^{i} \notin L$.
- If the machine fails to halt in the allotted time, we set $B_{i}=B_{i-1}$, but we know that the same machine will appear in the enumeration with an index sufficiently large.

## The Limits of Diagonalization

- As we saw, an oracle can transfer us to an alternative computational "universe". (We saw a universe where $\mathbf{P}=\mathbf{N P}$, and another where $\mathbf{P} \neq \mathbf{N P}$ )
- Diagonalization is a technique that relies in the facts that:
- TMs are (effectively) represented by strings.
- A TM can simulate another without much overhead in time/space.
- So, diagonalization or any other proof technique relies only on these two facts, holds also for every oracle.
- Such results are called relativizing results.
E.g., $\mathbf{P}^{A} \subseteq \mathbf{N} \mathbf{P}^{A}$, for every $A \in\{0,1\}^{*}$.
- The above two theorems indicate that $\mathbf{P}$ vs. NP is a nonrelativizing result, so diagonalization and any other relativizing method doesn't suffice to prove it.

## Cook Reductions

- A problem $A$ is Cook-Reducible to a problem $B$, denoted by $A \leq_{T}^{p} B$, if there is an oracle DTM $M^{B}$ which in polynomial time decides $A$ (making at most polynomial many queries to $B)$.
- That is: $A \in \mathbf{P}^{B}$
- Karp Reducibility $\Rightarrow$ Turing Reducibility
- $\bar{A} \leq_{T}^{p} A$

Theorem
P, PSPACE are closed under $\leq_{T}^{P}$.

- Is NP closed under $\leq_{T}^{p}$ ?

## *Random Oracles

- We proved that:
- $\exists A \subseteq \Sigma^{*}: \mathbf{P}^{A}=\mathbf{N P}^{A}$
- $\exists B \subseteq \Sigma^{*}: \mathbf{P}^{B} \neq \mathbf{N P}^{B}$
-What if we chose the oracle language at random?

## *Random Oracles

- We proved that:
- $\exists A \subseteq \Sigma^{*}: \mathbf{P}^{A}=\mathbf{N P}^{A}$
- $\exists B \subseteq \Sigma^{*}: \mathbf{P}^{B} \neq \mathbf{N P}^{B}$
- What if we chose the oracle language at random?
- Now, consider the set $\mathcal{U}=\operatorname{Pow}\left(\Sigma^{*}\right)$, and the sets:

$$
\begin{aligned}
& \left\{A \in \mathcal{U}: \mathbf{P}^{A}=\mathbf{N} \mathbf{P}^{A}\right\} \\
& \left\{B \in \mathcal{U}: \mathbf{P}^{B} \neq \mathbf{N P}^{B}\right\}
\end{aligned}
$$

- Can we compare these two sets, and find which is larger?

## *Random Oracles

- We proved that:
- $\exists A \subseteq \Sigma^{*}: \mathbf{P}^{A}=\mathbf{N P}^{A}$
- $\exists B \subseteq \Sigma^{*}: \mathbf{P}^{B} \neq \mathbf{N P}^{B}$
- What if we chose the oracle language at random?
- Now, consider the set $\mathcal{U}=\operatorname{Pow}\left(\Sigma^{*}\right)$, and the sets:

$$
\begin{aligned}
& \left\{A \in \mathcal{U}: \mathbf{P}^{A}=\mathbf{N} \mathbf{P}^{A}\right\} \\
& \left\{B \in \mathcal{U}: \mathbf{P}^{B} \neq \mathbf{N P}^{B}\right\}
\end{aligned}
$$

- Can we compare these two sets, and find which is larger?

Theorem (Bennet, Gill)

$$
\operatorname{Pr}_{B \subseteq \Sigma^{*}}\left[\mathbf{P}^{B} \neq \mathbf{N} \mathbf{P}^{B}\right]=1
$$

## The Polynomial Hierarchy

Polynomial Hierarchy Definition

- $\Delta_{0}^{p}=\Sigma_{0}^{p}=\Pi_{0}^{p}=\mathbf{P}$
- $\Delta_{i+1}^{p}=\mathbf{P}^{\Sigma_{i}^{p}}$
- $\Sigma_{i+1}^{p}=\mathbf{N P}^{\Sigma_{i}^{p}}$
- $\Pi_{i+1}^{p}=\operatorname{coNP}{ }^{\Sigma_{i}^{p}}$

$$
\mathbf{P H} \equiv \bigcup_{i \geqslant 0} \Sigma_{i}^{p}
$$

- $\Sigma_{0}^{p}=\mathbf{P}$
- $\Delta_{1}^{p}=\mathbf{P}, \Sigma_{1}^{p}=\mathbf{N P}, \Pi_{1}^{p}=\mathbf{c o N P}$
- $\Delta_{2}^{p}=\mathbf{P}^{N P}, \Sigma_{2}^{p}=\mathbf{N P} \mathbf{N P}^{N}, \Pi_{2}^{p}=c o \mathbf{N P}^{N P}$

Theorem
Let $L$ be a language, and $i \geq 1 . L \in \Sigma_{i}^{p}$ iff there is a polynomially balanced relation $R$ such that the language $\{x ; y:(x, y) \in R\}$ is in $\Pi_{i-1}^{p}$ and

$$
L=\{x: \exists y, \text { s.t. }:(x, y) \in R\}
$$

## Theorem

Let $L$ be a language, and $i \geq 1 . L \in \Sigma_{i}^{p}$ iff there is a polynomially balanced relation $R$ such that the language $\{x ; y:(x, y) \in R\}$ is in $\Pi_{i-1}^{p}$ and

$$
L=\{x: \exists y, \text { s.t. }:(x, y) \in R\}
$$

Proof (by Induction):

- For $i=1$ : $\{x ; y:(x, y) \in R\} \in \mathbf{P}$, so $L=\{x \mid \exists y:(x, y) \in R\} \in \mathbf{N P} \checkmark$

## Theorem

Let $L$ be a language, and $i \geq 1 . L \in \Sigma_{i}^{p}$ iff there is a polynomially balanced relation $R$ such that the language $\{x ; y:(x, y) \in R\}$ is in $\Pi_{i-1}^{p}$ and

$$
L=\{x: \exists y, \text { s.t. }:(x, y) \in R\}
$$

Proof (by Induction):

- For $i=1$ :
$\{x ; y:(x, y) \in R\} \in \mathbf{P}$, so $L=\{x \mid \exists y:(x, y) \in R\} \in \mathbf{N P} \checkmark$
- For $i>1$ :

If $\exists R \in \Pi_{i-1}^{p}$, we must show that $L \in \sum_{i}^{p} \Rightarrow$
$\exists$ NTM with $\sum_{i-1}^{p}$ oracle: $\operatorname{NTM}(x)$ guesses a $y$ and asks $\Pi_{i-1}^{p}$ oracle whether $(x, y) \notin R$.

## Proof (cont.):

If $L \in \Sigma_{i}^{p}$, we must show the existence or $R$ :

- $L \in \Sigma_{i}^{p} \Rightarrow \exists$ NTM $M^{K}, K \in \sum_{i-1}^{p}$, which decides $L$.
- $K \in \sum_{i-1}^{p} \Rightarrow \exists S \in \Pi_{i-2}^{p}:(z \in K \Leftrightarrow \exists w:(z, w) \in S)$.
- We must describe a relation $R$ (we know: $x \in L \Leftrightarrow$ accepting computation of $M^{K}(x)$ )
- Query Steps: "yes" $\rightarrow z_{i}$ has a certificate $w_{i}$ st $\left(z_{i}, w_{i}\right) \in S$.
- So, $R(x)=$ " $(x, y) \in R$ iff yrecords an accepting computation of $M^{\text {? }}$ on $x$, together with a certificate $w_{i}$ for each yes query $z_{i}$ in the computation."
- We must show $\{x ; y:(x, y) \in R\} \in \Pi_{i-1}^{p}$ :
- Check that all steps of $M^{\text {? }}$ are legal (poly time).
- Check that $\left(z_{i}, w_{i}\right) \in S\left(i n \Pi_{i-2}^{p}\right.$, and thus in $\left.\Pi_{i-1}^{p}\right)$.
- For all "no" queries $z_{i}^{\prime}$, check $z_{i}^{\prime} \notin K$ (another $\Pi_{i-1}^{p}$ ).

Corollary
Let $L$ be a language, and $i \geq 1 . L \in \Pi_{i}^{p}$ iff there is a polynomially balanced relation $R$ such that the language $\{x ; y:(x, y) \in R\}$ is in $\sum_{i-1}^{p}$ and

$$
L=\left\{x: \forall y,|y| \leq|x|^{k}, \text { s.t. }:(x, y) \in R\right\}
$$

Corollary
Let $L$ be a language, and $i \geq 1 . L \in \sum_{i}^{p}$ iff there is a polynomially balanced, polynomially-time decicable ( $i+1$ )-ary relation $R$ such that:

$$
L=\left\{x: \exists y_{1} \forall y_{2} \exists y_{3} \ldots Q y_{i}, \text { s.t. }:\left(x, y_{1}, \ldots, y_{i}\right) \in R\right\}
$$

where the $i^{\text {th }}$ quantifier $Q$ is $\forall$, if $i$ is even, and $\exists$, if $i$ is odd.

## Remark

$$
\Sigma_{i}^{p}=(\underbrace{\exists \forall \exists \cdots Q_{i}}_{i \text { quantifiers }} / \underbrace{\forall \exists \forall \cdots Q_{i}}_{i \text { quantifiers }}) \quad \Pi_{i}^{p}=(\underbrace{\forall \exists \forall \cdots Q_{i}}_{i \text { quantifiers }} / \underbrace{\exists \forall \exists \cdots Q_{i}}_{i \text { quantifiers }})
$$

Remark

$$
\Sigma_{i}^{p}=(\underbrace{\exists \forall \exists \cdots Q_{i}}_{i \text { quantifiers }} / \underbrace{\forall \exists \forall \cdots Q_{i}}_{i \text { quantifiers }}) \quad \Pi_{i}^{p}=(\underbrace{\forall \exists \forall \cdots Q_{i}}_{i \text { quantifiers }} / \underbrace{\exists \forall \exists \cdots Q_{i}}_{i \text { quantifiers }})
$$

Theorem
If for some $i \geq 1, \Sigma_{i}^{p}=\Pi_{i}^{p}$, then for all $j>i$ :

$$
\Sigma_{j}^{p}=\Pi_{j}^{p}=\Delta_{j}^{p}=\Sigma_{i}^{p}
$$

Or, the polynomial hierarchy collapses to the $i^{\text {th }}$ level.

## Proof:

- It suffices to show that: $\sum_{i}^{p}=\Pi_{i}^{p} \Rightarrow \sum_{i+1}^{p}=\Sigma_{i}^{p}$.
- Let $L \in \Sigma_{i+1}^{p} \Rightarrow \exists R \in \Pi_{i}^{p}: L=\{x \mid \exists y:(x, y) \in R\}$
- $\Pi_{i}^{p}=\Sigma_{i}^{p} \Rightarrow R \in \Sigma_{i}^{p}$
- $(x, y) \in R \Leftrightarrow \exists z:(x, y, z) \in S, S \in \Pi_{i-1}^{p}$.
- So, $x \in L \Leftrightarrow \exists y ; z:(x, y, z) \in S, S \in \Pi_{i-1}^{p}$, hence $L \in \sum_{i}^{p}$.

## Corollary

If $\mathbf{P}=\mathbf{N P}$, or even $\mathbf{N P}=$ coNP, the Polynomial Hierarchy collapses to the first level.

## Corollary

If $\mathbf{P}=\mathbf{N P}$, or even $\mathbf{N P}=$ coNP, the Polynomial Hierarchy collapses to the first level.

QSAT $_{i}$ Definition
Given expression $\phi$, with Boolean variables partitioned into $i$ sets $X_{i}$, is $\phi$ satisfied by the overall truth assignment of the expression:

$$
\exists X_{1} \forall X_{2} \exists X_{3} \ldots . . Q X_{i} \phi
$$

where Q is $\exists$ if $i$ is odd, and $\forall$ if $i$ is even.

Theorem
For all $i \geq 1$ QSAT $_{i}$ is $\sum_{i}^{p}$-complete.

## Theorem

If there is a PH-complete problem, then the polynomial hierarchy collapses to some finite level.

## Proof:

- Let $L$ is PH -complete.
- Since $L \in \mathbf{P H}, \exists i \geq 0: L \in \Sigma_{i}^{p}$.
- But any $L^{\prime} \in \sum_{i+1}^{p}$ reduces to $L$.
- Since PH is closed under reductions, we imply that $L^{\prime} \in \Sigma_{i}^{p}$, so $\sum_{i}^{p}=\Sigma_{i+1}^{p}$.

## Theorem

If there is a PH-complete problem, then the polynomial hierarchy collapses to some finite level.

Proof:

- Let $L$ is $\mathbf{P H}$-complete.
- Since $L \in \mathbf{P H}, \exists i \geq 0: L \in \Sigma_{i}^{p}$.
- But any $L^{\prime} \in \sum_{i+1}^{p}$ reduces to $L$.
- Since PH is closed under reductions, we imply that $L^{\prime} \in \Sigma_{i}^{p}$, so $\sum_{i}^{p}=\Sigma_{i+1}^{p}$.

Theorem
PH $\subseteq$ PSPACE

- PH $\stackrel{?}{=}$ PSPACE (Open). If it was, then PH has complete problems, so it collapses to some finite level.

## Relativized Results

Let's see how the inclusion of the Polynomial Hierarchy to Polynomial Space, and the inclusions of each level of PH to the next relativizes:

- $\mathbf{P H}^{A} \neq \mathbf{P S P A C E}^{A}$ relative to some oracle $A \subseteq \Sigma^{*}$. (Yao 1985, Håstad 1986)
- $\operatorname{Pr}_{A}\left[\mathbf{P H}^{A} \neq \operatorname{PSPACE}^{A}\right]=1$
(Cai 1986, Babai 1987)
- $(\forall i \in \mathbb{N}) \sum_{i}^{p, A} \subsetneq \sum_{i+1}^{p, A}$ relative to some oracle $A \subseteq \Sigma^{*}$.
(Yao 1985, Håstad 1986)
- $\operatorname{Pr}_{A}\left[(\forall i \in \mathbb{N}) \Sigma_{i}^{p, A} \subsetneq \Sigma_{i+1}^{p, A}\right]=1$
(Rossman-Servedio-Tan, 2015)

## Self-Reducibility of SAT

- For a Boolean formula $\phi$ with $n$ variables and $m$ clauses.
- It is easy to see that:

$$
\phi \in \mathrm{SAT} \Leftrightarrow\left(\left.\phi\right|_{x_{1}=0} \in \mathrm{SAT}\right) \vee\left(\left.\phi\right|_{x_{1}=1} \in \mathrm{SAT}\right)
$$

- Thus, we can self-reduce SAT to instances of smaller size.
- Self-Reducibility Tree of depth $n$ :

## Self-Reducibility of SAT

- For a Boolean formula $\phi$ with $n$ variables and $m$ clauses.
- It is easy to see that:

$$
\phi \in \mathrm{SAT} \Leftrightarrow\left(\left.\phi\right|_{x_{1}=0} \in \mathrm{SAT}\right) \vee\left(\left.\phi\right|_{x_{1}=1} \in \mathrm{SAT}\right)
$$

- Thus, we can self-reduce SAT to instances of smaller size.
- Self-Reducibility Tree of depth $n$ :

## Example

## Self-Reducibility of SAT

Definition (FSAT)
FSAT: Given a Boolean expression $\phi$, if $\phi$ is satisfiable then return a satisfying truth assignment for $\phi$. Otherwise return "no".

## Self-Reducibility of SAT

Definition (FSAT)
FSAT: Given a Boolean expression $\phi$, if $\phi$ is satisfiable then return a satisfying truth assignment for $\phi$. Otherwise return "no".

- FP is the function analogue of $\mathbf{P}$ : it contains functions computable by a DTM in poly-time.
- $\operatorname{FSAT} \in \mathbf{F P} \Rightarrow$ SAT $\in \mathbf{P}$.
- What about the opposite?

## Self-Reducibility of SAT

## Definition (FSAT)

FSAT: Given a Boolean expression $\phi$, if $\phi$ is satisfiable then return a satisfying truth assignment for $\phi$. Otherwise return "no".

- FP is the function analogue of $\mathbf{P}$ : it contains functions computable by a DTM in poly-time.
- $\operatorname{FSAT} \in \mathbf{F P} \Rightarrow$ SAT $\in \mathbf{P}$.
- What about the opposite?
- If SAT $\in \mathbf{P}$, we can use the self-reducibility property to fix variables one-by-one, and retrieve a solution.
- We only need $2 n$ calls to the alleged poly-time algorithm for SAT.

## What about TSP?

- We can solve TSP using a hypothetical algorithm for the NP-complete decision version of TSP:

## What about TSP?

- We can solve TSP using a hypothetical algorithm for the NP-complete decision version of TSP:
- We can find the cost of the optimum tour by binary search (in the interval $\left[0,2^{n}\right]$ ).
- When we find the optimum cost $C$, we fix it, and start changing intercity distances one-by one, by setting each distance to $C+1$.
- We then ask the NP-oracle if there still is a tour of optimum cost at most $C$ :
- If there is, then this edge is not in the optimum tour.
- If there is not, we know that this edge is in the optimum tour.
- After at most $n^{2}$ (polynomial) oracle queries, we can extract the optimum tour, and thus have the solution to TSP.

## The Classes $P^{N P}$ and $F^{N P}$

- $\mathbf{P}^{\text {SAT }}$ is the class of languages decided in pol time with a SAT oracle (Polynomial number of adaptive queries).
- SAT is NP-complete $\Rightarrow \mathbf{P}^{\text {SAT }}=\mathbf{P}^{\mathbf{N P}}$.
- $\mathbf{F P}^{N P}$ is the class of functions that can be computed by a poly-time DTM with a SAT oracle.
- FSAT, TSP $\in \mathbf{F P}^{N P}$.

## The Classes PNP and FPNP

- $\mathbf{P}^{\text {SAT }}$ is the class of languages decided in pol time with a SAT oracle (Polynomial number of adaptive queries).
- SAT is NP-complete $\Rightarrow \mathbf{P}^{\text {SAT }}=\mathbf{P}^{\mathbf{N P}}$.
- $\mathbf{F} \mathbf{P}^{N P}$ is the class of functions that can be computed by a poly-time DTM with a SAT oracle.
- FSAT, TSP $\in \mathbf{F P}^{N P}$.

Definition (Reductions for Function Problems)
A function problem $A$ reduces to $B$ if there exists $R, S \in \mathbf{F L}$ such that:

- $x \in A \Rightarrow R(x) \in B$.
- If $z$ is a correct output of $R(x)$, then $S(z)$ is a correct output of $x$.

Theorem
TSP is $\mathbf{F P}^{N P}$-complete.

## Warmup: Randomized Quicksort

## Deterministic Quicksort

Input: A list $L$ of integers;
If $\mathrm{n} \leq 1$ then return L .
Else \{

- let $i=1$;
- let $L_{1}$ be the sublist of $L$ whose elements are $<a_{i}$;
- let $L_{2}$ be the sublist of $L$ whose elements are $=a_{i}$;
- let $L_{3}$ be the sublist of $L$ whose elements are $>a_{i}$;
- Recursively Quicksort $\mathrm{L}_{1}$ and $\mathrm{L}_{3}$;
- return $\mathrm{L}=\mathrm{L}_{1} \mathrm{~L}_{2} \mathrm{~L}_{3}$;

## Warmup: Randomized Quicksort

## Randomized Quicksort

Input: A list $L$ of integers;
If $n \leq 1$ then return $L$.
Else \{

- choose a random integer i, $1 \leq i \leq n$;
- let $L_{1}$ be the sublist of $L$ whose elements are $<a_{i}$;
- let $L_{2}$ be the sublist of $L$ whose elements are $=a_{i}$;
- let $L_{3}$ be the sublist of $L$ whose elements are $>a_{i}$;
- Recursively Quicksort $\mathrm{L}_{1}$ and $\mathrm{L}_{3}$;
- return $\mathrm{L}=\mathrm{L}_{1} \mathrm{~L}_{2} \mathrm{~L}_{3}$;

## Warmup: Randomized Quicksort

- Let $T_{d}$ the max number of comparisons for the Deterministic Quicksort:

$$
\begin{gathered}
T_{d}(n) \geq T_{d}(n-1)+\mathcal{O}(n) \\
\Downarrow \\
T_{d}(n)=\Omega\left(n^{2}\right)
\end{gathered}
$$

## Examples of Randomized Algorithms

## Warmup: Randomized Quicksort

- Let $T_{d}$ the max number of comparisons for the Deterministic Quicksort:

$$
\begin{gathered}
T_{d}(n) \geq T_{d}(n-1)+\mathcal{O}(n) \\
\Downarrow \\
T_{d}(n)=\Omega\left(n^{2}\right)
\end{gathered}
$$

- Let $T_{r}$ the expected number of comparisons for the Randomized Quicksort:

$$
T_{r} \leq \frac{1}{n} \sum_{j=0}^{n-1}\left[T_{r}(j)-T_{r}(n-1-j)\right]+\mathcal{O}(n)
$$

$\Downarrow$

$$
T_{r}(n)=\mathcal{O}(n \log n)
$$

## Warmup: Polynomial Identity Testing

(1) Two polynomials are equal if they have the same coefficients for corresponding powers of their variable.
2 A polynomial is identically zero if all its coefficients are equal to the additive identity element.
3 How we can test if a polynomial is identically zero?

## Warmup: Polynomial Identity Testing

(1) Two polynomials are equal if they have the same coefficients for corresponding powers of their variable.
2 A polynomial is identically zero if all its coefficients are equal to the additive identity element.
3 How we can test if a polynomial is identically zero?
4 We can choose uniformly at random $r_{1}, \ldots, r_{n}$ from a set $S \subseteq \mathbb{F}$.
5 We are wrong with a probability at most:
Theorem (Schwartz-Zippel Lemma)
Let $Q\left(x_{1}, \ldots, x_{n}\right) \in \mathbb{F}\left[x_{1}, \ldots, x_{n}\right]$ be a multivariate polynomial of total degree $d$. Fix any finite set $S \subseteq \mathbb{F}$, and let $r_{1}, \ldots, r_{n}$ be chosen indepedently and uniformly at random from $S$. Then:

$$
\operatorname{Pr}\left[Q\left(r_{1}, \ldots, r_{n}\right)=0 \mid Q\left(x_{1}, \ldots, x_{n}\right) \neq 0\right] \leq \frac{d}{|S|}
$$

## Warmup: Polynomial Identity Testing

## Proof:

(By Induction on $n$ )

- For $n=1: \operatorname{Pr}[Q(r)=0 \mid Q(x) \neq 0] \leq d /|S|$
- For $n$ :

$$
Q\left(x_{1}, \ldots, x_{n}\right)=\sum_{i=0}^{k} x_{1}^{i} Q_{i}\left(x_{2}, \ldots, x_{n}\right)
$$

where $k \leq d$ is the largest exponent of $x_{1}$ in $Q$. $\operatorname{deg}\left(Q_{k}\right) \leq d-k \Rightarrow \operatorname{Pr}\left[Q_{k}\left(r_{2}, \ldots, r_{n}\right)=0\right] \leq(d-k) /|S|$ Suppose that $Q_{k}\left(r_{2}, \ldots, r_{n}\right) \neq 0$. Then:

$$
q\left(x_{1}\right)=Q\left(x_{1}, r_{2}, \ldots, r_{n}\right)=\sum_{i=0}^{k} x_{1}^{i} Q_{i}\left(r_{2}, \ldots, r_{n}\right)
$$

$\operatorname{deg}\left(q\left(x_{1}\right)\right)=k$, and $q\left(x_{1}\right) \neq 0$ !

## Warmup: Polynomial Identity Testing

Proof (cont'd):
The base case now implies that:

$$
\operatorname{Pr}\left[q\left(r_{1}\right)=Q\left(r_{1}, \ldots, r_{n}\right)=0\right] \leq k /|S|
$$

Thus, we have shown the following two equalities:

$$
\begin{gathered}
\operatorname{Pr}\left[Q_{k}\left(r_{2}, \ldots, r_{n}\right)=0\right] \leq \frac{d-k}{|S|} \\
\operatorname{Pr}\left[Q_{k}\left(r_{1}, r_{2}, \ldots, r_{n}\right)=0 \mid Q_{k}\left(r_{2}, \ldots, r_{n}\right) \neq 0\right] \leq \frac{k}{|S|}
\end{gathered}
$$

Using the following identity: $\operatorname{Pr}\left[\mathcal{E}_{1}\right] \leq \operatorname{Pr}\left[\mathcal{E}_{1} \mid \overline{\mathcal{E}}_{2}\right]+\operatorname{Pr}\left[\mathcal{E}_{2}\right]$ we obtain that the requested probability is no more than the sum of the above, which proves our theorem! $\square$

## Probabilistic Turing Machines

- A Probabilistic Turing Machine is a TM as we know it, but with access to a "random source", that is an extra (read-only) tape containing random-bits!
- Randomization on:
- Output (one or two-sided)
- Running Time

Definition (Probabilistic Turing Machines)
A Probabilistic Turing Machine is a TM with two transition functions $\delta_{0}, \delta_{1}$. On input $x$, we choose in each step with probability $1 / 2$ to apply the transition function $\delta_{0}$ or $\delta_{1}$, indepedently of all previous choices.

- We denote by $M(x)$ the random variable corresponding to the output of $M$ at the end of the process.
- For a function $T: \mathbb{N} \rightarrow \mathbb{N}$, we say that $M$ runs in $T(|x|)$-time if it halts on $x$ within $T(|x|)$ steps (regardless of the random choices it makes).

## BPP Class

Definition (BPP Class)
For $T: \mathbb{N} \rightarrow \mathbb{N}$, let BPTIME[T(n)] the class of languages $L$ such that there exists a PTM which halts in $\mathcal{O}(T(|x|))$ time on input $x$, and $\operatorname{Pr}[M(x)=L(x)] \geq 2 / 3$.
We define:

$$
\mathrm{BPP}=\bigcup_{c \in \mathbb{N}} \mathrm{BPTIME}\left[n^{c}\right]
$$

- The class BPP represents our notion of efficient (randomized) computation!
- We can also define BPP using certificates:

## BPP Class

Definition (Alternative Definition of BPP)
A language $L \in \mathbf{B P P}$ if there exists a poly-time TM $M$ and a polynomial $p \in \operatorname{poly}(n)$, such that for every $x \in\{0,1\}^{*}$ :

$$
\mathbf{P r}_{r \in\{0,1\}^{p(n)}}[M(x, r)=L(x)] \geq \frac{2}{3}
$$

- $\mathbf{P} \subseteq B P P$
- $\mathbf{B P P} \subseteq E X P$
- The "P vs BPP" question.

## Quantifier Characterizations

- Proper formalism (Zachos et al.):

Definition (Majority Quantifier)
Let $R:\{0,1\}^{*} \times\{0,1\}^{*} \rightarrow\{0,1\}$ be a predicate, and $\varepsilon$ a rational number, such that $\varepsilon \in\left(0, \frac{1}{2}\right)$. We denote by $\left(\exists^{+} y,|y|=k\right) R(x, y)$ the following predicate:
"There exist at least $\left(\frac{1}{2}+\varepsilon\right) \cdot 2^{k}$ strings $y$ of length $m$ for which $R(x, y)$ holds."

We call $\exists^{+}$the overwhelming majority quantifier.

- $\exists_{r}^{+}$means that the fraction $r$ of the possible certificates of a certain length satisfy the predicate for the certain input.

## Quantifier Characterizations

## Definition

We denote as $\mathcal{C}=\left(Q_{1} / Q_{2}\right)$, where $Q_{1}, Q_{2} \in\left\{\exists, \forall, \exists^{+}\right\}$, the class
$\mathcal{C}$ of languages $L$ satisfying:

- $x \in L \Rightarrow Q_{1} y R(x, y)$
- $x \notin L \Rightarrow Q_{2} y \neg R(x, y)$
- $\mathbf{P}=(\forall / \forall)$
- NP $=(\exists / \forall)$
- coNP $=(\forall / \exists)$
- $\mathbf{B P P}=\left(\exists^{+} / \exists^{+}\right)=\operatorname{coBPP}$

## RP Class

- In the same way, we can define classes that contain problems with one-sided error:

Definition
The class RTIME[T(n)] contains every language $L$ for which there exists a PTM $M$ running in $\mathcal{O}(T(|x|))$ time such that:

- $x \in L \Rightarrow \operatorname{Pr}[M(x)=1] \geq \frac{2}{3}$
- $x \notin L \Rightarrow \operatorname{Pr}[M(x)=0]=1$

We define

$$
\mathbf{R P}=\bigcup_{c \in \mathbb{N}} \mathbf{R T I M E}\left[n^{c}\right]
$$

- Similarly we define the class coRP.

## Quantifier Characterizations

- $\mathbf{R P} \subseteq \mathbf{N P}$, since every accepting "branch" is a certificate!
- $\mathbf{R P} \subseteq \mathbf{B P P}, c o \mathbf{R P} \subseteq \mathbf{B P P}$
- $\mathbf{R P}=\left(\exists^{+} / \forall\right)$

## Quantifier Characterizations

- $\mathbf{R P} \subseteq \mathbf{N P}$, since every accepting "branch" is a certificate!
- $\mathbf{R P} \subseteq \mathbf{B P P}, c o \mathbf{R P} \subseteq \mathbf{B P P}$
- $\mathbf{R P}=\left(\exists^{+} / \forall\right) \subseteq(\exists / \forall)=\mathbf{N P}$

## Quantifier Characterizations

- $\mathbf{R P} \subseteq \mathbf{N P}$, since every accepting "branch" is a certificate!
- $\mathbf{R P} \subseteq \mathbf{B P P}, c o \mathbf{R P} \subseteq \mathbf{B P P}$
- $\mathbf{R P}=\left(\exists^{+} / \forall\right) \subseteq(\exists / \forall)=\mathbf{N P}$
- coRP $=\left(\forall / \exists^{+}\right) \subseteq(\forall / \exists)=\operatorname{coNP}$

## Quantifier Characterizations

- $\mathbf{R P} \subseteq \mathbf{N P}$, since every accepting "branch" is a certificate!
- $\mathbf{R P} \subseteq \mathbf{B P P}, c o \mathbf{R P} \subseteq \mathbf{B P P}$
- $\mathbf{R P}=\left(\exists^{+} / \forall\right) \subseteq(\exists / \forall)=\mathbf{N P}$
- coRP $=\left(\forall / \exists^{+}\right) \subseteq(\forall / \exists)=\operatorname{coNP}$

Theorem (Decisive Characterization of BPP)

$$
\mathbf{B P P}=\left(\exists^{+} / \exists^{+}\right)=\left(\exists^{+} \forall / \forall \exists^{+}\right)=\left(\forall \exists^{+} / \exists^{+} \forall\right)
$$

## Quantifier Characterizations

## Proof:

- Let $L \in \mathbf{B P P}$. Then, by definition, there exists a polynomial-time computable predicate $Q$ and a polynomial $q$ such that for all $x$ 's of length $n$ :

$$
\begin{gathered}
x \in L \Rightarrow \exists^{+} y Q(x, y) \\
x \notin L \Rightarrow \exists^{+} y \neg Q(x, y)
\end{gathered}
$$

Swapping Lemma

$$
\begin{aligned}
& \text { (i) } \forall y \exists^{+} z R(x, y, z) \Rightarrow \exists^{+} C \forall y \bigvee_{z \in C} R(x, y, z) \\
& \text { (ii) } \forall z \exists^{+} y R(x, y, z) \Rightarrow \forall C \exists^{+} y \bigwedge_{z \in C} R(x, y, z)
\end{aligned}
$$

- By the above Lemma: $x \in L \Rightarrow \exists^{+} z Q(x, z) \Rightarrow$ $\forall y \exists^{+} z Q(x, y \oplus z) \Rightarrow \exists^{+} C \forall y[\exists(z \in C) Q(x, y \oplus z)]$, where $C$ denotes (as in the Swapping's Lemma formulation) a set of $q(n)$ strings, each of length $q(n)$.

## Quantifier Characterizations

Proof (cont'd):

- On the other hand, $x \notin L \Rightarrow \exists^{+} y \neg Q(x, z) \Rightarrow$ $\forall z \exists^{+} y \neg Q(x, y \oplus z) \Rightarrow \forall C \exists^{+} y[\forall(z \in C) \neg Q(x, y \oplus z)]$.
- Now, we only have to assure that the appeared predicates $\exists z \in C Q(x, y \oplus z)$ and $\forall z \in C \neg Q(x, y \oplus z)$ are computable in polynomial time
- Recall that in Swapping Lemma's formulation we demanded $|C| \leq p(n)$ and that for each $v \in C:|v|=p(n)$. This means that we seek if a string of polynomial length exists, or if the predicate holds for all such strings in a set with polynomial cardinality, procedure which can be surely done in polynomial time.

## Quantifier Characterizations

Proof (cont'd):

- Conversely, if $L \in\left(\exists^{+} \forall / \forall \exists^{+}\right)$, for each string $w,|w|=2 p(n)$, we have $w=w_{1} w_{2},\left|w_{1}\right|=\left|w_{2}\right|=p(n)$. Then:
$x \in L \Rightarrow \exists^{+} y \forall z R(x, y, z) \Rightarrow \exists^{+} w R\left(x, w_{1}, w_{2}\right)$
$x \notin L \Rightarrow \forall y \exists^{+} z R(x, y, z) \Rightarrow \exists^{+} w \neg R\left(x, w_{1}, w_{2}\right)$
- So, $L \in$ BPP. $\square$
- The above characterization is decisive, in the sense that if we replace $\exists^{+}$with $\exists$, the two predicates are still complementary (i.e. $R_{1} \Rightarrow \neg R_{2}$ ), so they still define a complexity class.
- In the above characterization of BPP, if we replace $\exists^{+}$with $\exists$, we obtain very easily a well-known result:

Corollary (Sipser-Gács Theorem)

$$
\mathrm{BPP} \subseteq \Sigma_{2}^{p} \cap \Pi_{2}^{p}
$$

## ZPP Class

- And now something completely different:
- What is the random variable was the running time and not the output?

## ZPP Class

- And now something completely different:
- What is the random variable was the running time and not the output?
- We say that $M$ has expected running time $T(n)$ if the expectation $\mathbf{E}\left[T_{M(x)}\right]$ is at most $T(|x|)$ for every $x \in\{0,1\}^{*}$. ( $T_{M(x)}$ is the running time of $M$ on input $x$, and it is a random variable!)

## Definition

The class ZTIME[T(n)] contains all languages $L$ for which there exists a machine $M$ that runs in an expected time $\mathcal{O}(T(|x|))$ such that for every input $x \in\{0,1\}^{*}$, whenever $M$ halts on $x$, the output $M(x)$ it produces is exactly $L(x)$. We define:

$$
\mathbf{Z P P}=\bigcup_{c \in \mathbb{N}} \mathbf{Z T I M E}\left[n^{c}\right]
$$

## ZPP Class

- The output of a ZPP machine is always correct!
- The problem is that we aren't sure about the running time.
- We can easily see that $\mathbf{Z P P}=\mathbf{R P} \cap$ coRP.
- The next Hasse diagram summarizes the previous inclusions: (Recall that $\Delta \Sigma_{2}^{p}=\Sigma_{2}^{p} \cap \Pi_{2}^{p}=\mathbf{N P} \mathbf{N P}^{\mathrm{N}} \cap \operatorname{coNP}{ }^{\mathbf{N P}}$ )

## PSPACE

## PSPACE

## Error Reduction for BPP

Theorem (Error Reduction for BPP)
Let $L \subseteq\{0,1\}^{*}$ be a language and suppose that there exists a poly-time PTM M such that for every $x \in\{0,1\}^{*}$ :

$$
\operatorname{Pr}[M(x)=L(x)] \geq \frac{1}{2}+|x|^{-c}
$$

Then, for every constant $d>0, \exists$ poly-time PTM $M^{\prime}$ such that for every $x \in\{0,1\}^{*}$ :

$$
\operatorname{Pr}\left[M^{\prime}(x)=L(x)\right] \geq 1-2^{-|x|^{d}}
$$

Proof: The machine $M^{\prime}$ does the following:

- Run $M(x)$ for every input $x$ for $k=8|x|^{2 c+d}$ times, and obtain outputs $y_{1}, y_{2}, \ldots, y_{k} \in\{0,1\}$.
- If the majority of these outputs is 1 , return 1
- Otherwise, return 0.

We define the r.v. $X_{i}$ for every $i \in[k]$ to be 1 if $y_{i}=L(x)$ and 0 otherwise.
$X_{1}, X_{2}, \ldots, X_{k}$ are indepedent Boolean r.v.'s, with:

$$
\mathbf{E}\left[X_{i}\right]=\operatorname{Pr}\left[X_{i}=1\right] \geq p=\frac{1}{2}+|x|^{-c}
$$

Applying a Chernoff Bound we obtain:

## Error Reduction

## Intermission: Chernoff Bounds

- How many samples do we need in order to estimate $\mu$ up to an error of $\pm \varepsilon$ with probability at least $1-\delta$ ?
- Chernoff Bound tells us that this number is $\mathcal{O}\left(\rho / \varepsilon^{2}\right)$, where $\rho=\log (1 / \delta)$.
- The probability that $k$ is $\rho \sqrt{n}$ far from $\mu n$ decays exponentially with $\rho$.

## Error Reduction

## Intermission: Chernoff Bounds

$$
\begin{aligned}
& \operatorname{Pr}\left[\sum_{i=1}^{n} X_{i} \geq(1+\delta) \mu\right] \leq\left[\frac{e^{\delta}}{(1+\delta)^{1+\delta}}\right]^{\mu} \\
& \operatorname{Pr}\left[\sum_{i=1}^{n} x_{i} \leq(1-\delta) \mu\right] \leq\left[\frac{e^{-\delta}}{(1-\delta)^{1-\delta}}\right]^{\mu}
\end{aligned}
$$

Other useful form is:

$$
\operatorname{Pr}\left[\left|\sum_{i=1}^{n} X_{i}-\mu\right| \geq c \mu\right] \leq 2 e^{-\min \left\{c^{2} / 4, c / 2\right\} \cdot \mu}
$$

- This probability is bounded by $2^{-\Omega(\mu)}$.

## Error Reduction for BPP

- From the above we can obtain the following interesting corollary:

Corollary
For $c>0$, let $\mathbf{B P P}_{1 / 2+n^{-c}}$ denote the class of languages $L$ for which there is a polynomial-time PTM $M$ satisfying $\operatorname{Pr}[M(x)=L(x)] \geq 1 / 2+|x|^{-c}$ for every $x \in\{0,1\}^{*}$. Then:

$$
\mathbf{B P P}_{1 / 2+n^{-c}}=\mathbf{B P P}
$$

- Obviously, $\exists^{+}=\exists_{1 / 2+\varepsilon}^{+}=\exists_{2 / 3}^{+}=\exists_{3 / 4}^{+}=\exists_{0.99}^{+}=\exists_{1-2^{-p(|x|)}}^{+}$

## Semantic vs. Syntactic Classes

- Every NPTM defines some language in NP: $x \in L \Leftrightarrow$ \#accepting paths $\neq 0$
- We can get an effective enumeration of all NPTMs, each deciding an NP language.
- But not every NPTM decides a language in RP: e.g., the NPTM that has exactly one accepting path.
- In this case, there is no way to tell whether the machine will always halt with the certified output. We call these classes semantic.
- So we have:
- Syntactic Classes (like P, NP)
- Semantic Classes (like RP, BPP, NP $\cap$ coNP, TFNP)

## Complete Problems for BPP?

- Any syntactic class has a "free" complete problem:

$$
\{\langle M, x\rangle: M \in \mathcal{M} \& M(x)=\text { "yes" }\}
$$

where $\mathcal{M}$ is the class of TMs of the variant that defines the class

- In semantic classes, this complete language is usually undecidable (Rice's Theorem).
- The defining property of BPTIME machines is semantic!
- If finally $\mathbf{P}=\mathbf{B P P}$, then BPP will have complete problems!!
- For the same reason, in semantic classes we cannot prove Hierarchy Theorems using Diagonalization.

## The Class PP

Definition
A language $L \in \mathbf{P P}$ if there exists an NPTM $M$, such that for every $x \in\{0,1\}^{*}: x \in L$ if and only if more than half of the computations of $M$ on input $x$ accept.

- Or, equivalently:

Definition
A language $L \in \mathbf{P P}$ if there exists a poly-time TM $M$ and a polynomial $p \in \operatorname{poly}(n)$, such that for every $x \in\{0,1\}^{*}$ :

$$
x \in L \Leftrightarrow\left|\left\{y \in\{0,1\}^{p(|x|)}: M(x, y)=1\right\}\right| \geq \frac{1}{2} \cdot 2^{p(|x|)}
$$

## The Class PP

- The defining property of PP is syntactic, any NPTM can define a language in PP.
- Due to the lack of a gap between the two cases, we cannot amplify the probability with polynomially many repetitions, as in the case of BPP.
- PP is closed under complement.
- A breakthrough result of R. Beigel, N. Reingold and D. Spielman is that PP is closed under intersection!

## The Class PP

- The defining property of PP is syntactic, any NPTM can define a language in PP.
- Due to the lack of a gap between the two cases, we cannot amplify the probability with polynomially many repetitions, as in the case of BPP.
- PP is closed under complement.
- A breakthrough result of R. Beigel, N. Reingold and D. Spielman is that PP is closed under intersection!
- The syntactic definition of PP gives the possibility for complete problems:
- Consider the problem MAJSAT:

Given a Boolean Expression, is it true that the majority of the $2^{n}$ truth assignments to its variables (that is, at least $2^{n-1}+1$ of them) satisfy it?

## Error Reduction

## The Class PP

## Theorem <br> MAJSAT is PP-complete!

- MAJSAT is not likely in NP, since the (obvious) certificate is not very succinct!

## Error Reduction

## The Class PP

## Theorem <br> MAJSAT is PP-complete!

- MAJSAT is not likely in NP, since the (obvious) certificate is not very succinct!

Theorem
$\mathbf{N P} \subseteq \mathbf{P P} \subseteq \mathbf{P S P A C E}$

## The Class PP

## Theorem <br> MAJSAT is PP-complete!

- MAJSAT is not likely in NP, since the (obvious) certificate is not very succinct!

Theorem

## $\mathbf{N P} \subseteq \mathbf{P P} \subseteq \mathbf{P S P A C E}$

## Proof:

It is easy to see that $\mathbf{P P} \subseteq$ PSPACE:
We can simulate any PP machine by enumerating all strings $y$ of length $p(n)$ and verify whether PP machine accepts. The PSPACE machine accepts if and only if there are more than $2^{p(n)-1}$ such $y^{\prime}$ s (by using a counter).

## The Class PP

Proof (cont'd):
Now, for $\mathbf{N P} \subseteq \mathbf{P P}$, let $A \in \mathbf{N P}$. That is, $\exists p \in p o l y(n)$ and a poly-time and balanced predicate $R$ such that:

$$
x \in A \Leftrightarrow(\exists y,|y|=p(|x|)): R(x, y)
$$

Consider the following TM:
$M$ accepts input ( $x$, by), with $|b|=1$ and $|y|=p(|x|)$, if and only if $R(x, y)=1$ or $b=1$.

- If $x \in A$, then $\exists$ at least one $y$ s.t. $R(x, y)$.

Thus, $\operatorname{Pr}[M(x)$ accepts $] \geq 1 / 2+2^{-(p(n)+1)}$.

- If $x \notin A$, then $\operatorname{Pr}[M(x)$ accepts $]=1 / 2$.

## Error Reduction

## Other Results

## Theorem

If $\mathbf{N P} \subseteq \mathbf{B P P}$, then $\mathbf{N P}=\mathbf{R P}$.

## Other Results

Theorem
If $\mathbf{N P} \subseteq \mathbf{B P P}$, then $\mathbf{N P}=\mathbf{R P}$.

## Proof:

- RP is closed under $\leq_{m}^{p}$-reducibility.
- It suffices to show that if $S A T \in \mathbf{B P P}$, then $S A T \in \mathbf{R P}$.
- Recall that SAT has the self-reducibility property: $\phi\left(x_{1}, \ldots, x_{n}\right): \phi \in \operatorname{SAT} \Leftrightarrow\left(\left.\left.\phi\right|_{x_{1}=0} \in \operatorname{SAT} \vee \phi\right|_{x_{1}=1} \in \operatorname{SAT}\right)$.
- SAT $\in$ BPP: $\exists$ PTM $M$ computing SAT with error probability bounded by $2^{-|\phi|}$.
- We can use the self-reducibility of SAT to produce a truth assignment for $\phi$ as follows:

## Other Results

Proof (cont'd):

Input: A Boolean formula $\phi$ with $n$ variables
If $M(\phi)=0$ then reject $\phi$;
For $i=1$ to $n$
$\rightarrow$ If $M\left(\left.\phi\right|_{x_{1}=\alpha_{1}, \ldots, x_{i-1}=\alpha_{i-1}, x_{i}=0}\right)=1$ then let $\alpha_{i}=0$
$\rightarrow$ Elself $M\left(\left.\phi\right|_{x_{1}=\alpha_{1}, \ldots, x_{i-1}=\alpha_{i-1}, x_{i}=1}\right)=1$ then let $\alpha_{i}=1$
$\rightarrow$ Else reject $\phi$ and halt;
If $\left.\phi\right|_{x_{1}=\alpha_{1}, \ldots, x_{n}=\alpha_{n}}=1$ then accept $F$
Else reject $F$

## Other Results

Proof (cont'd):

Input: A Boolean formula $\phi$ with $n$ variables
If $M(\phi)=0$ then reject $\phi$;
For $i=1$ to $n$
$\rightarrow$ If $M\left(\left.\phi\right|_{x_{1}=\alpha_{1}, \ldots, x_{i-1}=\alpha_{i-1}, x_{i}=0}\right)=1$ then let $\alpha_{i}=0$
$\rightarrow$ Elself $M\left(\left.\phi\right|_{x_{1}=\alpha_{1}, \ldots, x_{i-1}=\alpha_{i-1}, x_{i}=1}\right)=1$ then let $\alpha_{i}=1$
$\rightarrow$ Else reject $\phi$ and halt;
If $\left.\phi\right|_{x_{1}=\alpha_{1}, \ldots, x_{n}=\alpha_{n}}=1$ then accept $F$
Else reject $F$

- Note that $M_{1}$ accepts $\phi$ only if a t.a. $t\left(x_{i}\right)=\alpha_{i}$ is found.
- Therefore, $M_{1}$ never makes mistakes if $\phi \notin$ SAT.
- If $\phi \in$ SAT, then $M$ rejects $\phi$ on each iteration of the loop w.p. $2^{-|\phi|}$.
- So, $\operatorname{Pr}\left[M_{1}\right.$ accepting $\left.x\right]=\left(1-2^{-|\phi|}\right)^{n}$, which is greater than $1 / 2$ if $|\phi| \geq n>1$. $\square$

## Relativized Results

## Theorem

Relative to a random oracle $A, \mathbf{P}^{A}=\mathbf{B P} \mathbf{P}^{A}$. That is,

$$
\operatorname{Pr}_{A \in\{0,1\}^{*}}\left[\mathbf{P}^{A}=\mathbf{B P P}^{A}\right]=1
$$

Also,

- $\mathbf{B P P}^{A} \subsetneq \mathbf{N P}^{A}$, relative to a random oracle $A$.
- There exists an $A$ such that: $\mathbf{P}^{A} \neq \mathbf{R P}^{A}$.
- There exists an $A$ such that: $\mathbf{R P}^{A} \neq c o \mathbf{R} \mathbf{P}^{A}$
- There exists an $A$ such that: $\mathbf{R P}^{A} \neq \mathbf{N} \mathbf{P}^{A}$.

## Relativized Results

Theorem
Relative to a random oracle $A, \mathbf{P}^{A}=\mathbf{B P} \mathbf{P}^{A}$. That is,

## Boolean Circuits

- A Boolean Circuit is a natural model of nonuniform computation, a generalization of hardware computational methods.
- A non-uniform computational model allows us to use a different "algorithm" to be used for every input size, in contrast to the standard (or uniform) Turing Machine model, where the same T.M. is used on (infinitely many) input sizes.
- Each circuit can be used for a fixed input size, which limits or model.

## Definition (Boolean circuits)

For every $n \in \mathbb{N}$ an $n$-input, single output Boolean Circuit $C$ is a directed acyclic graph with $n$ sources and one sink.

- All nonsource vertices are called gates and are labeled with one of $\wedge$ (and), $\vee$ (or) or $\neg$ (not).
- The vertices labeled with $\wedge$ and $\vee$ have fan-in (i.e. number or incoming edges) 2.
- The vertices labeled with $\neg$ have fan-in 1 .
- The size of $C$, denoted by $|C|$, is the number of vertices in it.
- For every vertex $v$ of $C$, we assign a value as follows: for some input $x \in\{0,1\}^{n}$, if $v$ is the $i$-th input vertex then $\operatorname{val}(v)=x_{i}$, and otherwise val( $v$ ) is defined recursively by applying $v$ 's logical operation on the values of the vertices connected to $v$.
- The output $C(x)$ is the value of the output vertex.
- The depth of $C$ is the length of the longest directed path from an input node to the output node.
- To overcome the fixed input length size, we need to allow families (or sequences) of circuits to be used:

Definition
Let $T: \mathbb{N} \rightarrow \mathbb{N}$ be a function. A $T(n)$-size circuit family is a sequence $\left\{C_{n}\right\}_{n \in \mathbb{N}}$ of Boolean circuits, where $C_{n}$ has $n$ inputs and a single output, and its size $\left|C_{n}\right| \leq T(n)$ for every $n$.

- These infinite families of circuits are defined arbitrarily: There is no pre-defined connection between the circuits, and also we haven't any "guarantee" that we can construct them efficiently.
- Like each new computational model, we can define a complexity class on it by imposing some restriction on a complexity measure:

Definition
We say that a language $L$ is in $\operatorname{SIZE}(T(n))$ if there is a $T(n)$-size circuit family $\left\{C_{n}\right\}_{n \in \mathbb{N}}$, such that $\forall x \in\{0,1\}^{n}$ :

$$
x \in L \Leftrightarrow C_{n}(x)=1
$$

Definition
$\mathbf{P}_{\text {/poly }}$ is the class of languages that are decidable by polynomial size circuits families. That is,

$$
\mathbf{P} / \text { poly }=\bigcup_{c \in \mathbb{N}} \operatorname{SIZE}\left(n^{c}\right)
$$

Theorem (Nonuniform Hierarchy Theorem)
For every functions $T, T^{\prime}: \mathbb{N} \rightarrow \mathbb{N}$ with $\frac{2^{n}}{n}>T^{\prime}(n)>10 T(n)>n$, $\operatorname{SIZE}(T(n)) \subsetneq \operatorname{SIZE}\left(T^{\prime}(n)\right)$

## Turing Machines that take advice

Definition
Let $T, a: \mathbb{N} \rightarrow \mathbb{N}$. The class of languages decidable by $T(n)$-time Turing Machines with $a(n)$ bits of advice, denoted

DTIME $(T(n) / a(n))$
containts every language $L$ such that there exists a sequence $\left\{a_{n}\right\}_{n \in \mathbb{N}}$ of strings, with $a_{n} \in\{0,1\}^{a(n)}$ and a Turing Machine $M$ satisfying:

$$
x \in L \Leftrightarrow M\left(x, a_{n}\right)=1
$$

for every $x \in\{0,1\}^{n}$, where on input $\left(x, a_{n}\right)$ the machine $M$ runs for at most $\mathcal{O}(T(n))$ steps.

## Turing Machines that take advice

Theorem (Alternative Definition of $\mathrm{P}_{/ \text {poly }}$ )

$$
\mathbf{P}_{/ \text {poly }}=\bigcup_{c, d \in \mathbb{N}} \operatorname{DTIME}\left(n^{c} / n^{d}\right)
$$

## Turing Machines that take advice

Theorem (Alternative Definition of $\mathbf{P} /$ poly $)$

$$
\mathbf{P}_{/ \text {poly }}=\bigcup_{c, d \in \mathbb{N}} \operatorname{DTIME}\left(n^{c} / n^{d}\right)
$$

Proof: $(\subseteq)$ Let $L \in \mathbf{P}_{/ \text {poly }}$. Then, $\exists\left\{C_{n}\right\}_{n \in \mathbb{N}}: C_{|x|}=L(x)$. We can use $C_{n}$ 's encoding as an advice string for each $n$.

## Turing Machines that take advice

Theorem (Alternative Definition of $\mathrm{P}_{\text {/poly }}$ )

$$
\mathbf{P}_{/ \text {poly }}=\bigcup_{c, d \in \mathbb{N}} \operatorname{DTIME}\left(n^{c} / n^{d}\right)
$$

Proof: $(\subseteq)$ Let $L \in \mathbf{P}_{/ \text {poly }}$. Then, $\exists\left\{C_{n}\right\}_{n \in \mathbb{N}}: C_{|x|}=L(x)$. We can use $C_{n}$ 's encoding as an advice string for each $n$. $(\supseteq)$ Let $L \in \operatorname{DTIME}\left(n^{c} / n^{d}\right)$. Then, since CVP is $\mathbf{P}$-complete, we construct for every $n$ a circuit $D_{n}$ such that, for $x \in\{0,1\}^{n}, a_{n} \in\{0,1\}^{a(n)}:$

$$
D_{n}\left(x, a_{n}\right)=M\left(x, a_{n}\right)
$$

Then, let $C_{n}(x)=D_{n}\left(x, a_{n}\right)$ (We hard-wire the advice string!) Since $a(n)=n^{d}$, the circuits have polynomial size. $\square$.

## $\mathbf{P} \subsetneq \mathbf{P}_{/ \text {poly }}$

- For the subset inclusion, recall that CVP is P-complete.
- But why proper inclusion?
- Consider the following language: $\mathrm{U}=\left\{1^{n} \mid n \in \mathbb{N}\right\}$.
- $\mathrm{U} \in \mathbf{P}_{\text {/poly }}$.
- Now consider this:
$\mathrm{U}_{\mathrm{H}}=\left\{1^{n} \mid n\right.$ 's binary expression encodes a pair $\llcorner M, x\lrcorner$ s.t. $\left.M(x) \downarrow\right\}$
- It is easy to see that $U_{H} \in \mathbf{P}_{\text {/poly }}$, but....

Theorem (Karp-Lipton Theorem)
If $\mathbf{N P} \subseteq \mathbf{P}_{/ \text {poly }}$, then $\mathbf{P H}=\Sigma_{2}^{p}$.

Theorem (Karp-Lipton Theorem)
If $\mathbf{N P} \subseteq \mathbf{P}_{/ \text {poly }}$, then $\mathbf{P H}=\Sigma_{2}^{p}$.

## Proof Sketch:

- It suffices to show that $\Pi_{2}^{p} \subseteq \Sigma_{2}^{p}$. (Recall that $\Sigma_{2}^{p}=\Pi_{2}^{p} \Rightarrow \mathbf{P H}=\Sigma_{2}^{p}$ )
- Let $L \in \Pi_{2}^{p}$. Then, $x \in L \Rightarrow \forall y \exists z R(x, y, z)$

Theorem (Karp-Lipton Theorem)
If $\mathbf{N P} \subseteq \mathbf{P}_{/ \text {poly }}$, then $\mathbf{P H}=\Sigma_{2}^{p}$.

## Proof Sketch:

- It suffices to show that $\Pi_{2}^{p} \subseteq \Sigma_{2}^{p}$. (Recall that $\Sigma_{2}^{p}=\Pi_{2}^{p} \Rightarrow \mathbf{P H}=\Sigma_{2}^{p}$ )
- Let $L \in \Pi_{2}^{p}$. Then, $x \in L \Rightarrow \forall y \underbrace{\exists z R(x, y, z)}_{\text {SAT Question }}$

Theorem (Karp-Lipton Theorem)
If $\mathbf{N P} \subseteq \mathbf{P}_{/ \text {poly }}$, then $\mathbf{P H}=\Sigma_{2}^{p}$.

## Proof Sketch:

- It suffices to show that $\Pi_{2}^{p} \subseteq \Sigma_{2}^{p}$. (Recall that $\Sigma_{2}^{p}=\Pi_{2}^{p} \Rightarrow \mathbf{P H}=\Sigma_{2}^{p}$ )
- Let $L \in \Pi_{2}^{p}$. Then, $x \in L \Rightarrow \forall y \underbrace{\exists z R(x, y, z)}_{\text {SAT Question }}$
- So, we can get a function $\phi(x, y) \in \mathbf{F P}$ s.t. :

$$
x \in L \Leftrightarrow \forall y[\phi(x, y) \in \mathrm{SAT}]
$$

- Since SAT $\in \mathbf{P}_{/ \text {poly }}, \exists\left\{C_{n}\right\}_{n \in \mathbb{N}}$ s.t. $C_{|\phi|}(\phi(x, y))=1$ iff $\phi$ satisfiable.
- The idea is to nondeterministically guess such a circuit:
- If $x \in L$ :

Since $L \in \Pi_{2}^{p}, x \in L \Rightarrow \forall y[\phi(x, y) \in$ SAT $]$ We will guess a correct $C$, and $\forall y \phi(x, y)$ will be satisfiable, so $C$ will accept all $y$ 's:

$$
x \in L \Rightarrow \exists C \forall y[C(\phi(x, y))=1]
$$

- If $x \notin L$ :

Since $L \in \Pi_{2}^{p}, x \notin L \Rightarrow \exists y[\phi(x, y) \notin$ SAT]
Then, there will be a $y_{0}$ for which $\phi\left(x, y_{0}\right)$ is not satisfiable. So, for all guesses of $C, \phi\left(x, y_{0}\right)$ will always be rejected:

$$
x \notin L \Rightarrow \forall C \exists y[C(\phi(x, y))=0]
$$

- That is a $\Sigma_{2}^{p}$ question, so $L \in \Sigma_{2}^{p} \Rightarrow \Pi_{2}^{p} \subseteq \Sigma_{2}^{p}$.

Theorem (Meyer's Theorem) If $\mathbf{E X P} \subseteq \mathbf{P}_{/ \text {poly }}$, then $\mathbf{E X P}=\Sigma_{2}^{p}$.

Theorem

## $\mathbf{B P P} \subsetneq \mathbf{P}_{/ \text {poly }}$

Proof: Recall that if $L \in \mathbf{B P P}$, then $\exists$ PTM $M$ such that:

$$
\operatorname{Pr}_{r \in\{0,1\}^{\text {poly }(n)}}[M(x, r) \neq L(x)]<2^{-n}
$$

Then, taking the union bound:

$$
\begin{aligned}
\operatorname{Pr}[\exists x & \left.\in\{0,1\}^{n}: M(x, r) \neq L(x)\right]=\operatorname{Pr}\left[\bigcup_{x \in\{0,1\}^{n}} M(x, r) \neq L(x)\right] \leq \\
& \leq \sum_{x \in\{0,1\}^{n}} \operatorname{Pr}[M(x, r) \neq L(x)]<2^{-n}+\cdots+2^{-n}=1
\end{aligned}
$$

So, $\exists r_{n} \in\{0,1\}^{\text {poly }(n)}$, s.t. $\forall x\{0,1\}^{n}: M\left(x, r_{n}\right)=L(x)$.
Using $\left\{r_{n}\right\}_{n \in \mathbb{N}}$ as advice string, we have the non-uniform machine.

Definition (Circuit Complexity or Worst-Case Hardness)
For a finite Boolean Function $f:\{0,1\}^{n} \rightarrow\{0,1\}$, we define the (circuit) complexity of $f$ as the size of the smallest Boolean Circuit computing $f$ (that is, $C(x)=f(x), \forall x \in\{0,1\}^{n}$ ).

Definition (Average-Case Hardness)
The minimum $S$ such that there is a circuit $C$ of size $S$ such that:

$$
\operatorname{Pr}[C(x)=f(x)] \geq \frac{1}{2}+\frac{1}{S}
$$

is called the (average-case) hardness of $f$.

## Hierarchies for Semantic Classes with advice

- We have argued why we can't obtain Hierarchies for semantic measures using classical diagonalization techniques. But using small advice we can have the following results:

Theorem ([Bar02], [GST04])
For $a, b \in \mathbb{R}$, with $1 \leq a<b$ : $\operatorname{BPTIME}\left(n^{a}\right) / 1 \varsubsetneqq \operatorname{BPTIME}\left(n^{b}\right) / 1$

Theorem ([FST05])
For any $1 \leq a \in \mathbb{R}$ there is a real $b>$ a such that:
$\operatorname{RTIME}\left(n^{b}\right) / 1 \varsubsetneqq \operatorname{RTIME}\left(n^{a}\right) / \log (n)^{1 / 2 a}$

## Uniform Families of Circuits

- We saw that $\mathbf{P}_{\text {/poly }}$ contains an undecidable language.
- The root of this problem lies in the "weak" definition of such families, since it suffices that $\exists$ a circuit family for $L$.
- We haven't a way (or an algorithm) to construct such a family.
- So, may be useful to restrict or attention to families we can construct efficiently:

Theorem (P-Uniform Families)
A circuit family $\left\{C_{n}\right\}_{n \in \mathbb{N}}$ is $\mathbf{P}$-uniform if there is a polynomial-time T.M. that on input $1^{n}$ outputs the description of the circuit $C_{n}$.

Theorem
A language $L$ is computable by a $\mathbf{P}$-uniform circuit family iff $L \in \mathbf{P}$.

- We can define in the same way logspace-uniform circuit families, constructed by logspace-TMs.

## Parallel Computations

- Circuits are a useful model for parallel computations.
- Number of processors $\sim$ Circuit Size Parallel time $\sim$ Circuit Depth

## Parallel Computations

- Circuits are a useful model for parallel computations.
- Number of processors $\sim$ Circuit Size Parallel time $\sim$ Circuit Depth

Definition (Class NC)
A language $L$ is in $\mathbf{N C}^{i}$ if $L$ is decided by a logspace-uniform circuit family $\left\{C_{n}\right\}_{n \in \mathbb{N}}$, where $C_{n}$ has gates with fan-in 2 , poly $(n)$ size and $\mathcal{O}\left(\log ^{i} n\right)$ depth.

$$
\mathbf{N C}=\bigcup_{i \in \mathbb{N}} \mathbf{N C}^{i}
$$

## Parallel Computations

Definition (Class AC)
A language $L$ is in $\mathbf{A C}^{i}$ if $L$ is decided by a logspace-uniform circuit family $\left\{C_{n}\right\}_{n \in \mathbb{N}}$, where $C_{n}$ has gates with unbounded fan-in, poly $(n)$ size and $\mathcal{O}\left(\log ^{i} n\right)$ depth.

$$
\mathbf{A C}=\bigcup_{i \in \mathbb{N}} \mathbf{A C}^{i}
$$

- $\mathbf{N C}^{i} \subseteq \mathbf{A C}^{i} \subseteq \mathbf{N C}^{i+1}$, for all $i \geq 0$
- $\mathbf{N C} \subseteq \mathbf{P}$
- $\mathbf{N C}^{1} \subseteq \mathbf{L} \subseteq \mathbf{N L} \subseteq \mathbf{N C}^{2}$
- NC ${ }^{i} \subseteq$ DSPACE $\left[\log ^{i} n\right]$, for all $i \geq 0$
- PARITY $\in \mathbf{N C}^{1}$.

## Circuit Lower Bounds

- The significance of proving lower bounds for this computational model is related to the famous " $\mathbf{P}$ vs NP" problem, since:

$$
\mathbf{N P} \backslash \mathbf{P} / \text { poly } \neq \emptyset \Rightarrow \mathbf{P} \neq \mathbf{N P}
$$

- But...after decades of efforts, The best lower bound for an NP language is $5 n-o(n)$, proved very recently (2005).
- There are better lower bounds for some special cases, i.e. some restricted classes of circuits, such as: bounded depth circuits, monotone circuits, and bounded depth circuits with "counting" gates.

Reminder
Let PAR: $\{0,1\}^{n} \rightarrow\{0,1\}$ be the parity function, which outputs the modulo 2 sum of an $n$-bit input. That is:

$$
\operatorname{PAR}\left(x_{1}, \ldots, x_{n}\right) \equiv \sum_{i=1}^{n} x_{i}(\bmod 2)
$$

Theorem (Furst, Saxe, Sipser, Ajtai)

## PARITY $\notin \mathbf{A C}^{0}$

- The above result (improved by Håstad and Yao) gives a relatively tight lower bound of $\exp \left(\Omega\left(n^{1 /(d-1)}\right)\right)$, on the size of $n$-input PAR circuits of depth $d$.

Corollary
$\mathbf{N C}^{0} \neq \mathbf{A C}^{0} \neq \mathbf{N C}^{1}$

Definition
A language $L$ is in $\mathbf{A C C}^{0}\left[m_{1}, \ldots, m_{k}\right]$ if there is a circuit family $\left\{C_{n}\right\}_{n \in \mathbb{N}}$ where $C_{n}$ has gates with unbounded fan-in, poly $(n)$ size and $\mathcal{O}(1)$ depth, and $M O D_{m_{1}}, \ldots, M O D_{m_{k}}$ gates accepting $L$.

$$
\mathbf{A C C}^{0}=\bigcup_{m_{1}, \ldots, m_{k}} \mathbf{A C C}^{0}\left[m_{1}, \ldots, m_{k}\right]
$$

- A $M O D_{m}$ gate outputs 0 if the sum of its inputs is $0 \operatorname{modm}$, and 1 otherwise.

Theorem (Razborov-Smolensky, 1987)
For district primes $p$ and $q$, the function $M O D_{p}$ is not in $\mathbf{A C C}^{0}[q]$.
Theorem (Ryan Williams, 2010)

Definition
For $x, y \in\{0,1\}^{n}$, we denote $x \preceq y$ if every bit that is 1 in $x$ is also 1 in $y$. A function $f:\{0,1\}^{n} \rightarrow\{0,1\}$ is monotone if $f(x) \leq f(y)$ for every $x \preceq y$.

Definition
A Boolean Circuit is monotone if it contains only AND and OR gates, and no NOT gates. Such a circuit can only compute monotone functions.

Theorem (Razborov, Andreev, Alon, Boppana)
Denote by $C L I Q \cup E_{k, n}:\{0,1\}\binom{n}{2} \rightarrow\{0,1\}$ the function that on input an adjacency matrix of an n-vertex graph $G$ outputs 1 iff $G$ contains an $k$-clique. There exists some constant $\epsilon>0$ such that for every $k \leq n^{1 / 4}$, there is no monotone circuit of size less than $2^{\epsilon \sqrt{k}}$ that computes CLIQUE $k, n$.

- This is a significant lower bound $\left(2^{\Omega\left(n^{1 / 8}\right)}\right)$.
- The importance of the above theorem lies on the fact that there was some alleged connection between monotone and non-monotone circuit complexity (e.g. that they would be polynomially related). Unfortunately, Éva Tardos proved in 1988 that the gap between the two complexities is exponential.
- Where is the problem finally?

Today, we know that a result for a lower bound using such techniques would imply the inversion of strong one-way functions:

## *Natural Proofs [Razborov, Rudich 1994]

## Definition

Let $\mathcal{P}$ be the predicate:
"A Boolean function $f:\{0,1\}^{n} \rightarrow\{0,1\}$ doesn't have $n^{c}$-sized circuits for some $c \geq 1$."
$\mathcal{P}(f)=0, \forall f \in \operatorname{SIZE}\left(n^{c}\right)$ for a $c \geq 1$. We call this $n^{c}$-usefulness.
A predicate $\mathcal{P}$ is natural if:

- There is an algorithm $M \in \mathbf{E}$ such that for a function $g:\{0,1\}^{n} \rightarrow\{0,1\}: M(g)=\mathcal{P}(g)$.
- For a random function $g: \operatorname{Pr}[\mathcal{P}(g)=1] \geq \frac{1}{n}$

Theorem
If strong one-way functions exist, then there exists a constant $c \in \mathbb{N}$ such that there is no $n^{c}$-useful natural predicate $\mathcal{P}$.

## Introduction

"Maybe Fermat had a proof! But an important party was certainly missing to make the proof complete: the verifier. Each time rumor gets around that a student somewhere proved $\mathbf{P}=\mathbf{N P}$, people ask "Has Karp seen the proof?" (they hardly even ask the student's name). Perhaps the verifier is most important that the prover." (from [BM88])

- The notion of a mathematical proof is related to the certificate definition of NP.
- We enrich this scenario by introducing interaction in the basic scheme:
The person (or TM) who verifies the proof asks the person who provides the proof a series of "queries", before he is convinced, and if he is, he provide the certificate.

## Introduction

- The first person will be called Verifier, and the second Prover.
- In our model of computation, Prover and Verifier are interacting Turing Machines.
- We will categorize the various proof systems created by using:
- various TMs (nondeterministic, probabilistic etc)
- the information exchanged (private/public coins etc)
- the number of TMs (IPs, MIPs,...)

## Warmup: Interactive Proofs with deterministic Verifier

Definition (Deterministic Proof Systems)
We say that a language $L$ has a $k$-round deterministic interactive proof system if there is a deterministic Turing Machine $V$ that on input $x, \alpha_{1}, \alpha_{2}, \ldots, \alpha_{i}$ runs in time polynomial in $|x|$, and can have a $k$-round interaction with any TM $P$ such that:

- $x \in L \Rightarrow \exists P:\langle V, P\rangle(x)=1$ (Completeness)
- $x \notin L \Rightarrow \forall P:\langle V, P\rangle(x)=0$ (Soundness)

The class dIP contains all languages that have a $k$-round deterministic interactive proof system, where $p$ is polynomial in the input length.

- $\langle V, P\rangle(x)$ denotes the output of $V$ at the end of the interaction with $P$ on input $x$, and $\alpha_{i}$ the exchanged strings.
- The above definition does not place limits on the computational power of the Prover!

## Warmup: Interactive Proofs with deterministic Verifier

- But...

Theorem

$$
\mathbf{d I P}=\mathbf{N P}
$$

## Proof: Trivially, NP $\subseteq$ dIP.

Let $L \in \mathbf{d I P}$ :

- A certificate is a transcript $\left(\alpha_{1}, \ldots, \alpha_{k}\right)$ causing $V$ to accept, i.e. $V\left(x, \alpha_{1}, \ldots, \alpha_{k}\right)=1$.
- We can efficiently check if $V(x)=\alpha_{1}, V\left(x, \alpha_{1}, \alpha_{2}\right)=\alpha_{3}$ etc...
- If $x \in L$ such a transcript exists!
- Conversely, if a transcript exists, we can define define a proper $P$ to satisfy: $P\left(x, \alpha_{1}\right)=\alpha_{2}, P\left(x, \alpha_{1}, \alpha_{2}, \alpha_{3}\right)=\alpha_{4}$ etc., so that $\langle V, P\rangle(x)=1$, so $x \in L$.
- So $L \in \mathbf{N P}$ ! $\square$

## Probabilistic Verifier: The Class IP

- We saw that if the verifier is a simple deterministic TM, then the interactive proof system is described precisely by the class NP.
- Now, we let the verifier be probabilistic, i.e. the verifier's queries will be computed using a probabilistic TM:

Definition (Goldwasser-Micali-Rackoff)
For an integer $k \geq 1$ (that may depend on the input length), a language $L$ is in IP $k$ ] if there is a probabilistic polynomial-time T.M. $V$ that can have a $k$-round interaction with a T.M. $P$ such that:

- $x \in L \Rightarrow \exists P: \operatorname{Pr}[\langle V, P\rangle(x)=1] \geq \frac{2}{3}$ (Completeness)
- $x \notin L \Rightarrow \forall P: \operatorname{Pr}[\langle V, P\rangle(x)=1] \leq \frac{1}{3}$ (Soundness)

## Probabilistic Verifier: The Class IP

Definition
We also define:

$$
\mathbf{I P}=\bigcup_{c \in \mathbb{N}} \mathbf{I P}\left[n^{c}\right]
$$

- The "output" $\langle V, P\rangle(x)$ is a random variable.
- We'll see that IP is a very large class! $(\supseteq \mathbf{P H})$
- As usual, we can replace the completeness parameter $2 / 3$ with $1-2^{-n^{s}}$ and the soundness parameter $1 / 3$ by $2^{-n^{s}}$, without changing the class for any fixed constant $s>0$.
- We can also replace the completeness constant $2 / 3$ with 1 (perfect completeness), without changing the class, but replacing the soundness constant $1 / 3$ with 0 , is equivalent with a deterministic verifier, so class IP collapses to NP.

## Interactive Proof for Graph Non-Isomorphism

Definition
Two graphs $G_{1}$ and $G_{2}$ are isomorphic, if there exists a permutation $\pi$ of the labels of the nodes of $G_{1}$, such that $\pi\left(G_{1}\right)=G_{2}$. If $G_{1}$ and $G_{2}$ are isomorphic, we write $G_{1} \cong G_{2}$.

- GI: Given two graphs $G_{1}, G_{2}$, decide if they are isomorphic.
- GNI: Given two graphs $G_{1}, G_{2}$, decide if they are not isomorphic.
- Obviously, GI $\in \mathbf{N P}$ and GNI $\in$ coNP.
- This proof system relies on the Verifier's access to a private random source which cannot be seen by the Prover, so we confirm the crucial role the private coins play.

## Interactive Proof for Graph Non-Isomorphism

Verifier: Picks $i \in\{1,2\}$ uniformly at random.
Then, it permutes randomly the vertices of $G_{i}$ to get a new graph $H$. Is sends $H$ to the Prover.
Prover: Identifies which of $G_{1}, G_{2}$ was used to produce $H$.
Let $G_{j}$ be the graph. Sends $j$ to $V$.
Verifier: Accept if $i=j$. Reject otherwise.

## Interactive Proof for Graph Non-Isomorphism

Verifier: Picks $i \in\{1,2\}$ uniformly at random.
Then, it permutes randomly the vertices of $G_{i}$ to get a new graph $H$. Is sends $H$ to the Prover.
Prover: Identifies which of $G_{1}, G_{2}$ was used to produce $H$.
Let $G_{j}$ be the graph. Sends $j$ to $V$.
Verifier: Accept if $i=j$. Reject otherwise.

- If $G_{1} \not \not G_{2}$, then the powerfull prover can (nondeterministically) guess which one of the two graphs is isomprphic to $H$, and so the Verifier accepts with probability 1.
- If $G_{1} \cong G_{2}$, the prover can't distinguish the two graphs, since a random permutation of $G_{1}$ looks exactly like a random permutation of $G_{2}$. So, the best he can do is guess randomly one, and the Verifier accepts with probability (at most) $1 / 2$, which can be reduced by additional repetitions.

## Babai's Arthur-Merlin Games

Definition (Extended (FGMSZ89))
An Arhur-Merlin Game is a pair of interactive TMs $A$ and $M$, and a predicate $R$ such that:

- On input $x$, exactly $2 q(|x|)$ messages of length $m(|x|)$ are exchanged, $q, m \in p o l y(|x|)$.
- A goes first, and at iteration $1 \leq i \leq q(|x|)$ chooses u.a.r. a string $r_{i}$ of length $m(|x|)$.
- M's reply in the $i^{\text {th }}$ iteration is $y_{i}=M\left(x, r_{1}, \ldots, r_{i}\right)$ (M's strategy).
- For every $M^{\prime}$, a conversation between $A$ and $M^{\prime}$ on input $x$ is $r_{1} y_{1} r_{2} y_{2} \cdots r_{q(|x|)} y_{q(|x|)}$.
- The set of all conversations is denoted by $\operatorname{CONV}_{x}^{M^{\prime}}$, $\left|\operatorname{CON} V_{x}^{M^{\prime}}\right|=2^{q(|x|) m(|x|)}$.

## Babai's Arthur-Merlin Games

Definition (cont'd)

- The predicate $R$ maps the input $x$ and a conversation to a Boolean value.
- The set of accepting conversations is denoted by $A C C_{x}^{R, M}$, and is the set:

$$
\left\{r_{1} \cdots r_{q} \mid \exists y_{1} \cdots y_{q} \text { s.t. } r_{1} y_{1} \cdots r_{q} y_{q} \in \operatorname{CON} V_{x}^{M} \wedge R\left(r_{1} y_{1} \cdots r_{q} y_{q}\right)=1\right\}
$$

- A language $L$ has an Arthur-Merlin proof system if:
- There exists a strategy for $M$, such that for all $x \in L$ : $\frac{A C C_{x}^{R, M}}{C O N V_{x}^{M}} \geq \frac{2}{3}$ (Completeness)
- For every strategy for $M$, and for every $x \notin L: \frac{A C C^{R, M}}{\operatorname{CON}_{x}^{M}} \leq \frac{1}{3}$ (Soundness)

## Definitions

- So, with respect to the previous IP definition:

## Definition

For every $k$, the complexity class $\mathbf{A M}[k]$ is defined as a subset to IP $[k]$ obtained when we restrict the verifier's messages to be random bits, and not allowing it to use any other random bits that are not contained in these messages.
We denote $\mathbf{A M} \equiv \mathbf{A M}[2]$.

## Definitions

- So, with respect to the previous IP definition:

Definition
For every $k$, the complexity class $\mathbf{A M}[k]$ is defined as a subset to IP [k] obtained when we restrict the verifier's messages to be random bits, and not allowing it to use any other random bits that are not contained in these messages.
We denote $\mathbf{A M} \equiv \mathbf{A M}[2]$.

- Merlin $\rightarrow$ Prover
- Arthur $\rightarrow$ Verifier

## Definitions

- So, with respect to the previous IP definition:

Definition
For every $k$, the complexity class $\mathbf{A M}[k]$ is defined as a subset to IP [ $k$ ] obtained when we restrict the verifier's messages to be random bits, and not allowing it to use any other random bits that are not contained in these messages.
We denote $\mathbf{A M} \equiv \mathbf{A M}[2]$.

- Merlin $\rightarrow$ Prover
- Arthur $\rightarrow$ Verifier
- Also, the class MA consists of all languages $L$, where there's an interactive proof for $L$ in which the prover first sending a message, and then the verifier is "tossing coins" and computing its decision by doing a deterministic polynomial-time computation involving the input, the message and the random output.

Arthur-Merlin Games

## Public vs. Private Coins

Theorem

## GNI $\in \mathbf{A M}[2]$

Theorem
For every $p \in \operatorname{poly}(n)$ :

$$
\mathbf{I P}(p(n))=\mathbf{A M}(p(n)+2)
$$

- So,

$$
\mathbf{I P}[p o l y]=\mathbf{A M}[p o l y]
$$

## Properties of Arthur-Merlin Games

- $\mathbf{M A} \subseteq \mathbf{A M}$
- $\mathbf{M A}[1]=\mathbf{N P}, \mathbf{A M}[1]=\mathbf{B P P}$
- AM could be intuitively approached as the probabilistic version of $\mathbf{N P}$ (usually denoted as $\mathbf{A M}=\mathcal{B P}$. NP).
- $\mathbf{A M} \subseteq \Pi_{2}^{p}$ and $\mathbf{M A} \subseteq \Sigma_{2}^{p} \cap \Pi_{2}^{p}$.
- $M A \subseteq N^{B P P}, M A^{B P P}=M A, A^{B P P}=A M$ and $\mathbf{A M}^{\Delta \Sigma_{1}^{p}}=\mathbf{A} \mathbf{M}^{\mathbf{N P} \cap c o N P}=\mathbf{A M}$
- If we consider the complexity classes $\mathbf{A M}[k]$ (the languages that have Arthur-Merlin proof systems of a bounded number of rounds, they form an hierarchy:

$$
\mathbf{A M}[0] \subseteq \mathbf{A M}[1] \subseteq \cdots \subseteq \mathbf{A M}[k] \subseteq \mathbf{A M}[k+1] \subseteq \cdots
$$

- Are these inclusions proper ? ? ?

## Properties of Arthur-Merlin Games

## Properties of Arthur-Merlin Games

- Proper formalism (Zachos et al.):

Definition (Majority Quantifier)
Let $R:\{0,1\}^{*} \times\{0,1\}^{*} \rightarrow\{0,1\}$ be a predicate, and $\varepsilon$ a rational number, such that $\varepsilon \in\left(0, \frac{1}{2}\right)$. We denote by $\left(\exists^{+} y,|y|=k\right) R(x, y)$ the following predicate:
"There exist at least $\left(\frac{1}{2}+\varepsilon\right) \cdot 2^{k}$ strings $y$ of length $m$ for which $R(x, y)$ holds."

We call $\exists^{+}$the overwhelming majority quantifier.

- $\exists_{r}^{+}$means that the fraction $r$ of the possible certificates of a certain length satisfy the predicate for the certain input.
- Obviously, $\exists^{+}=\exists_{1 / 2+\varepsilon}^{+}=\exists_{2 / 3}^{+}=\exists_{3 / 4}^{+}=\exists_{0.99}^{+}=\exists_{1-2^{-p(|x|)}}^{+}$

## Properties of Arthur-Merlin Games

Definition
We denote as $\mathcal{C}=\left(Q_{1} / Q_{2}\right)$, where $Q_{1}, Q_{2} \in\left\{\exists, \forall, \exists^{+}\right\}$, the class
$\mathcal{C}$ of languages $L$ satisfying:

- $x \in L \Rightarrow Q_{1} y R(x, y)$
- $x \notin L \Rightarrow Q_{2} y \neg R(x, y)$
- So: $\mathbf{P}=(\forall / \forall), \mathbf{N P}=(\exists / \forall)$, coNP $=(\forall / \exists)$

$$
\mathbf{B P P}=\left(\exists^{+} / \exists^{+}\right), \mathbf{R P}=\left(\exists^{+} / \forall\right), \operatorname{coRP}=\left(\forall / \exists^{+}\right)
$$

## Properties of Arthur-Merlin Games

Definition
We denote as $\mathcal{C}=\left(Q_{1} / Q_{2}\right)$, where $Q_{1}, Q_{2} \in\{\exists, \forall, \exists+\}$, the class
$\mathcal{C}$ of languages $L$ satisfying:

- $x \in L \Rightarrow Q_{1} y R(x, y)$
- $x \notin L \Rightarrow Q_{2} y \neg R(x, y)$
- So: $\mathbf{P}=(\forall / \forall), \mathbf{N P}=(\exists / \forall)$, coNP $=(\forall / \exists)$

$$
\mathbf{B P P}=\left(\exists^{+} / \exists^{+}\right), \mathbf{R P}=\left(\exists^{+} / \forall\right), \operatorname{coRP}=\left(\forall / \exists^{+}\right)
$$

Arthur-Merlin Games

$$
\begin{aligned}
& \mathbf{A M}=\mathcal{B P} \cdot \mathbf{N P}=\left(\exists^{+} \exists / \exists^{+} \forall\right) \\
& \mathbf{M A}=\mathcal{N} \cdot \mathbf{B P P}=\left(\exists \exists^{+} / \forall \exists^{+}\right)
\end{aligned}
$$

- Similarly: AMA $=\left(\exists^{+} \exists \exists^{+} / \exists^{+} \forall \exists^{+}\right)$etc.

## Properties of Arthur-Merlin Games

## Measure One Results

- $\mathbf{P}^{A} \neq \mathbf{N P}^{A}, \mathbf{P}^{A}=\mathbf{B P} \mathbf{P}^{A}, \mathbf{N P}^{A}=\mathbf{A M}^{A}$, for almost all oracles $A$.

Definition

$$
\text { almostC }=\left\{L \mid \operatorname{Pr}_{A \in\{0,1\}^{*}}\left[L \in \mathcal{C}^{A}\right]=1\right\}
$$

Theorem
(i) almost $\mathbf{P}=\mathbf{B P P}$ [BG81]
(ii almost NP $=\mathbf{A M}$ [NW94]
iii) almost $\mathbf{P H}=\mathbf{P H}$

Theorem (Kurtz)
For almost every pair of oracles $B, C$ :
(i) $\mathbf{B P P}=\mathbf{P}^{B} \cap \mathbf{P}^{C}$
(ii) almost $\mathbf{N P}=\mathbf{N} \mathbf{P}^{B} \cap \mathbf{N P}^{C}$

## The power of Interactive Proofs

- As we saw, Interaction alone does not gives us computational capabilities beyond NP.
- Also, Randomization alone does not give us significant power (we know that $\mathbf{B P P} \subseteq \Sigma_{2}^{p}$, and many researchers believe that $\mathbf{P}=\mathbf{B P P}$, which holds under some plausible assumptions).
- How much power could we get by their combination?
- We know that for fixed $k \in \mathbb{N}$, IP $[k]$ collapses to

$$
\mathbf{I P}[k]=\mathbf{A M}=\mathcal{B} \mathcal{P} \cdot \mathbf{N P}
$$

a class that is "close" to NP (under similar assumptions, the non-deterministic analogue of $\mathbf{P}$ vs. BPP is NP vs. AM.)

- If we let $k$ be a polynomial in the size of the input, how much more power could we get?

## The power of Interactive Proofs

- Surprisingly:

Theorem (L.F.K.N. \& Shamir)
$I P=P S P A C E$

## The power of Interactive Proofs

## Lemma 1

IP $\subseteq$ PSPACE

## The power of Interactive Proofs

## Lemma 1

## IP $\subseteq$ PSPACE

## Proof:

- If the Prover is an NP, or even a PSPACE machine, the lemma holds.
- But what if we have an omnipotent prover?
- On any input, the Prover chooses its messages in order to maximize the probability of V's acceptance!
- We consider the prover as an oracle, by assuming wlog that his responses are one bit at a time.
- The protocol has polynomially many rounds (say $N=n^{c}$ ), which bounds the messages and the random bits used.
- So, the protocol is described by a computation tree $T$ :

## The power of Interactive Proofs

Proof(cont'd):

- Vertices of $T$ are V's configurations.
- Random Branches (queries to the random tape)
- Oracle Branches (queries to the prover)
- For each fixed $P$, the tree $T_{P}$ can be pruned to obtain only random branches.
- Let $\operatorname{Pr}_{\text {opt }}[E \mid F]$ the conditional probability given that the prover always behaves optimally.
- The acceptance condition is $m_{N}=1$.
- For $y_{i} \in\{0,1\}^{N}$ and $z_{i} \in\{0,1\}$ let:

$$
\begin{aligned}
R_{i} & =\bigwedge_{j=1}^{i} m_{j}=y_{j} \\
S_{i} & =\bigwedge^{i} I_{j}=z_{j}
\end{aligned}
$$

## The power of Interactive Proofs

Proof(cont'd):

$$
\begin{gathered}
\operatorname{Pr}_{\text {opt }}\left[m_{N}=1 \mid R_{i-1} \wedge S_{i-1}\right]= \\
\sum_{y_{i}} \max _{z_{i}} \operatorname{Pr}_{\text {opt }}\left[m_{N}=1 \mid R_{i} \wedge S_{i}\right] \cdot \operatorname{Pr}_{\text {opt }}\left[R_{i} \mid R_{i-1} \wedge S_{i-1}\right]
\end{gathered}
$$

- $\operatorname{Pr}_{\text {opt }}\left[R_{i} \mid R_{i-1} \wedge S_{i-1}\right]$ is PSPACE-computable, by simulating V.
- $\operatorname{Pr}_{\text {opt }}\left[m_{N}=1 \mid R_{i} \wedge S_{i}\right]$ can be calculated by DFS on $T$.
- The probability of acceptance is $\operatorname{Pr}_{\text {opt }}\left[m_{N}=1\right]=\operatorname{Pr}_{\text {opt }}\left[m_{N}=1 \mid R_{0} \wedge S_{0}\right]$
- The prover can calculate its optimal move at any point in the protocol in PSPACE by calculating $\operatorname{Pr}_{\text {opt }}\left[m_{N}=1 \mid R_{i} \wedge S_{i}\right]$ for $z_{i}\{0,1\}$ and choosing its answer to be the value that gives the maximum.

## Warmup: Interactive Proof for UNSAT

## Lemma 2

## PSPACE $\subseteq I P$

- For simplicity, we will construct an Interactive Proof for UNSAT (a coNP-complete problem), showing that:

Theorem

## $\operatorname{coNP} \subseteq I P$

- Let $N$ be a prime.
- We will translate a formula $\phi$ with $m$ clauses and $n$ variables $x_{1}, \ldots, x_{n}$ to a polynomial $p$ over the field $(\bmod N)$ (where $\left.N>2^{n} \cdot 3^{m}\right)$, in the following way:

## Arithmetization

- Arithmetic generalization of a CNF Boolean Formula.

$$
\begin{aligned}
& \mathrm{T} \longrightarrow \\
& \mathrm{~F} \longrightarrow \\
& \neg \\
& \neg x \longrightarrow \\
& 1-x \\
& \wedge \longrightarrow \\
& \mathrm{~V} \longrightarrow \\
&+
\end{aligned}
$$

## Example

$$
\begin{gathered}
\left(x_{3} \vee \neg x_{5} \vee x_{17}\right) \wedge\left(x_{5} \vee x_{9}\right) \wedge\left(\neg x_{3} \vee x_{4}\right) \\
\downarrow \\
\left(x_{3}+\left(1-x_{5}\right)+x_{17}\right) \cdot\left(x_{5}+x_{9}\right) \cdot\left(\left(1-x_{3}\right)+\left(1-x_{4}\right)\right)
\end{gathered}
$$

- Each literal is of degree 1 , so the polynomial $p$ is of degree at most $m$.
- Also, $0<p<3^{m}$.

$\longrightarrow \quad$ checks if $q_{n}(0)+q_{n}(1)=q_{n-1}\left(r_{n-1}\right)$
picks $r_{n} \in\{0, \ldots, N-1\}$
checks if $q_{n}\left(r_{n}\right)=p\left(r_{1}, \ldots, r_{n}\right)$

## Warmup: Interactive Proof for UNSAT

- If $\phi$ is unsatisfiable,then

$$
\sum_{x_{1} \in\{0,1\}} \sum_{x_{2} \in\{0,1\}} \cdots \sum_{x_{n} \in\{0,1\}} p\left(x_{1}, \ldots, x_{n}\right) \equiv 0(\bmod N)
$$

and the protocol will succeed.

- Also, the arithmetization can be done in polynomial time, and if we take $N=2^{\mathcal{O}(n+m)}$, then the elements in the field can be represented by $\mathcal{O}(n+m)$ bits, and thus an evaluation of $p$ in any point of $\{0, \ldots, N-1\}$ can be computed in polynomial time.
- We have to show that if $\phi$ is satisfiable, then the verifier will reject with high probability.
- If $\phi$ is satisfiable, then
$\sum_{x_{1} \in\{0,1\}} \sum_{x_{2} \in\{0,1\}} \cdots \sum_{x_{n} \in\{0,1\}} p\left(x_{1}, \ldots, x_{n}\right) \neq 0(\bmod N)$
- So, $p_{1}(0)+p_{1}(1) \neq 0$, so if the prover send $p_{1}$ we 're done.
- If the prover send $q_{1} \neq p_{1}$, then the polynomials will agree on at most $m$ places. So, $\operatorname{Pr}\left[p_{1}\left(r_{1}\right) \neq q_{1}\left(r_{1}\right)\right] \geq 1-\frac{m}{N}$.
- If indeed $p_{1}\left(r_{1}\right) \neq q_{1}\left(r_{1}\right)$ and the prover sends $p_{2}=q_{2}$, then the verifier will reject since $q_{2}(0)+q_{2}(1)=p_{1}\left(r_{1}\right) \neq q_{1}\left(r_{1}\right)$.
- Thus, the prover must send $q_{2} \neq p_{2}$.
- We continue in a similar way: If $q_{i} \neq p_{i}$, then with probability at least $1-\frac{m}{N}, r_{i}$ is such that $q_{i}\left(r_{i}\right) \neq p_{i}\left(r_{i}\right)$.
- Then, the prover must send $q_{i+1} \neq p_{i+1}$ in order for the verifier not to reject.
- At the end, if the verifier has not rejected before the last check, $\operatorname{Pr}\left[p_{n} \neq q_{n}\right] \geq 1-(n-1) \frac{m}{N}$.
- If so, with probability at least $1-\frac{m}{N}$ the verifier will reject since, $q_{n}(x)$ and $p\left(r_{1}, \ldots, r_{n-1}, x\right)$ differ on at least that fraction of points.
- The total probability that the verifier will accept if at most $\frac{n m}{N}$.

## Arithmetization of QBF

$$
\begin{array}{lll}
\exists & \longrightarrow \\
\forall & \sum \\
\end{array}
$$

## Example

$$
\begin{gathered}
\forall x_{1} \exists x_{2}\left[\left(x_{1} \wedge x_{2}\right) \vee \exists x_{3}\left(\bar{x}_{2} \wedge x_{3}\right)\right] \\
\downarrow \\
\prod_{x_{1} \in\{0,1\}} \sum_{x_{2} \in\{0,1\}}\left[\left(x_{1} \cdot x_{2}\right)+\sum_{x_{3} \in\{0,1\}}\left(1-x_{2}\right) \cdot x_{3}\right]
\end{gathered}
$$

## Arithmetization of QBF

- But, every quantifier arithmetization may double the degree of each variable, leading to an exponential degree polynomial. The verifier can't read this.
- We can substitute the arithmetized polynomial with another, agreeing with the original only on all boolean assignments:
- Since if $x=0,1$ then $x^{i}=x$, for all $i$, we can just get rid of the exponents.
- So, we can arithmetize Quantified Boolean Formulas, and with slight modifications, the same protocol works.
- Remember that the TQBF problem is PSPACE-complete.
- Hence, PSPACE $\subseteq I P$.

## Epilogue: Probabilistically Checkable Proofs

- But if we put a proof instead of a Prover?

## Epilogue: Probabilistically Checkable Proofs

- But if we put a proof instead of a Prover?
- The alleged proof is a string, and the (probabilistic) verification procedure is given direct (oracle) access to the proof.
- The verification procedure can access only few locations in the proof!
- We parameterize these Interactive Proof Systems by two complexity measures:
- Query Complexity
- Randomness Complexity
- The effective proof length of a PCP system is upper-bounded by $q(n) \cdot 2^{r(n)}$ (in the non-adaptive case).

## PCP Definitions

Definition (PCP Verifiers)
Let $L$ be a language and $q, r: \mathbb{N} \rightarrow \mathbb{N}$. We say that $L$ has an $(r(n), q(n))$-PCP verifier if there is a probabilistic polynomial-time algorithm $V$ (the verifier) satisfying:

- Efficiency. On input $x \in\{0,1\}^{*}$ and given random oracle access to a string $\pi \in\{0,1\}^{*}$ of length at most $q(n) \cdot 2^{r(n)}$ (which we call the proof), $V$ uses at most $r(n)$ random coins and makes at most $q(n)$ non-adaptive queries to locations of $\pi$. Then, it accepts or rejects. Let $V^{\pi}(x)$ denote the random variable representing $V$ 's output on input $x$ and with random access to $\pi$.
- Completeness: If $x \in L$, then $\exists \pi \in\{0,1\}^{*}: \operatorname{Pr}\left[V^{\pi}(x)=1\right]=1$
- Soundness: If $x \notin L$, then $\forall \pi \in\{0,1\}^{*}: \operatorname{Pr}\left[V^{\pi}(x)=1\right] \leq \frac{1}{2}$ We say that a language $L$ is in $\operatorname{PCP}[r(n), q(n)]$ if $L$ has a $(\mathcal{O}(r(n)), \mathcal{O}(q(n)))$-PCP verifier.

## Main Results

- Obviously:
$\operatorname{PCP}[0,0]=?$ $\mathbf{P C P}[0$, poly $]=?$
$\mathbf{P C P}[p o l y, 0]=$ ?

## Main Results

- Obviously:
$\mathbf{P C P}[0,0]=\mathbf{P}$ $\mathbf{P C P}[0$, poly $]=$ ?
$\mathbf{P C P}[p o l y, 0]=$ ?

## Main Results

- Obviously:
$\mathbf{P C P}[0,0]=\mathbf{P}$
$\mathbf{P C P}[0$, poly $]=\mathbf{N P}$
$\mathbf{P C P}[p o l y, 0]=$ ?

## Main Results

- Obviously:
$\mathbf{P C P}[0,0]=\mathbf{P}$
$\mathbf{P C P}[0, p o l y]=\mathbf{N P}$
$\mathbf{P C P}[p o l y, 0]=c o R P$

## Main Results

- Obviously:
$\mathbf{P C P}[0,0]=\mathbf{P}$
$\mathbf{P C P}[0, p o l y]=\mathbf{N P}$
$\mathbf{P C P}[p o l y, 0]=c o \mathbf{R P}$
- A suprising result from Arora, Lund, Motwani, Safra, Sudan, Szegedy states that:

Theorem
$\mathbf{N P}=\mathbf{P C P}[\log n, 1]$

## Properties

- The restriction that the proof length is at most $q 2^{r}$ is inconsequential, since such a verifier can look on at most this number of locations.
- We have that $\operatorname{PCP}[r(n), q(n)] \subseteq \operatorname{NTIME}\left[2^{\mathcal{O}(r(n))} q(n)\right]$, since a NTM could guess the proof in $2^{\mathcal{O}(r(n))} q(n)$ time, and verify it deterministically by running the verifier for all $2^{\mathcal{O}(r(n))}$ possible choices of its random coin tosses. If the verifier accepts for all these possible tosses, then the NTM accepts.

- The map of NP
- Non-Uniform Complexity
- Interactive Proofs
- Inapproximability
- Derandomization of Complexity Classes
- Counting Complexity
- Epilogue

## Why counting?

- So far, we have seen two versions of problems:
- Decision Problems (if a solution exists)
- Function Problems (if a solution can be produced)
- A very important type of problems in Complexity Theory is also:
- Counting Problems (how many solutions exist)

## Example (\#SAT)

Given a Boolean Expression, compute the number of different truth assignments that satisfy it.

- Note that if we can solve \#SAT in polynomial time, we can solve SAT also.
- Similarly, we can define \#HAMILTON PATH, \#CLIQUE, etc.

## Basic Definitions

Definition（\＃P）
A function $f:\{0,1\}^{*} \rightarrow \mathbb{N}$ is in $\# \mathbf{P}$ if there exists a polynomial $p: \mathbb{N} \rightarrow \mathbb{N}$ and a polynomial－time Turing Machine $M$ such that for every $x \in\{0,1\}^{*}$ ：

$$
f(x)=\left|\left\{y \in\{0,1\}^{p(|x|)}: M(x, y)=1\right\}\right|
$$

－The definition implies that $f(x)$ can be expressed in poly $(|x|)$ bits．
－Each function $f$ in \＃P is equal to the number of paths from an initial configuration to an accepting configuration，or accepting paths in the configuration graph of a poly－time NDTM．
－ $\mathbf{F P} \subseteq \# \mathbf{P} \subseteq \mathbf{P S P A C E}$
－If $\# \mathbf{P}=\mathbf{F P}$ ，then $\mathbf{P}=\mathbf{N P}$ ．
－If $\mathbf{P}=\mathbf{P S P A C E}$ ，then $\# \mathbf{P}=\mathbf{F P}$ ．

## Counting Problems

- In order to formalize a notion of completeness for \#P , we must define proper reductions:

Definition (Cook Reduction)
A function $f$ is $\# \mathbf{P}$-complete if it is in $\# \mathbf{P}$ and every $g \in \# \mathbf{P}$ is in $\mathbf{F P}^{f}$.

- As we saw, for each problem in NP we can define the associated counting problem: If $A \in \mathbf{N P}$, then

$$
\# A(x)=\left|\left\{y \in\{0,1\}^{p(|x|)}: R_{A}(x, y)=1\right\}\right| \in \# \mathbf{P}
$$

## Counting Problems

- In order to formalize a notion of completeness for $\# \mathbf{P}$, we must define proper reductions:

Definition (Cook Reduction)
A function $f$ is $\# \mathbf{P}$-complete if it is in $\# \mathbf{P}$ and every $g \in \# \mathbf{P}$ is in $\mathbf{F P}^{f}$.

- As we saw, for each problem in NP we can define the associated counting problem: If $A \in \mathbf{N P}$, then

$$
\# A(x)=\left|\left\{y \in\{0,1\}^{p(|x|)}: R_{A}(x, y)=1\right\}\right| \in \# \mathbf{P}
$$

- We now define a more strict form of reduction:

## Counting Problems

Definition (Parsimonious Reduction)
We say that there is a parsimonious reduction from \#A to \#B if there is a polynomial time transformation $f$ such that for all $x$ :

$$
\left|\left\{y: R_{A}(x, y)=1\right\}\right|=\left|\left\{z: R_{B}(f(x), z)=1\right\}\right|
$$

- Or, using function notation:

Definition

$$
f \leq_{m}^{p} g \Longleftrightarrow \exists h \in \mathbf{F P}: \forall x f(x)=g(h(x))
$$

## Completeness Results

## Theorem

\#CIRCUIT SAT is \#P-complete.

## Proof:

- Let $f \in \# \mathbf{P}$. Then, $\exists M, p$ : $f(x)=\left|\left\{y \in\{0,1\}^{p(|x|)}: M(x, y)=1\right\}\right|$.
- Given $x$, we want to construct a circuit $C$ such that:

$$
|\{z: C(z)\}|=\left|\left\{y: y \in\{0,1\}^{p(|x|}, M(x, y)=1\right\}\right|
$$

- We can construct a circuit $\hat{C}$ such that on input $x, y$ simulates $M(x, y)$.
- We know that this can be done with a circuit with size about the square of $M$ 's running time.
- Let $C(y)=\hat{C}(x, y)$.

## Completeness Results

Theorem \#SAT is \# $\mathbf{P}$-complete.

## Proof:

- We reduce \#CIRCUIT SAT to \#SAT:
- Let a circuit $C$, with $x_{1}, \ldots, x_{n}$ input gates and $1, \ldots, m$ gates.
- We construct a Boolean formula $\phi$ with variables $x_{1}, \ldots, x_{n}, g_{1}, \ldots, g_{m}$, where $g_{i}$ represents the output of gate $i$.
- A gate can be complete described by simulating the output for each of the 4 possible inputs.
- In this way, we have reduced $C$ to a formula $\phi$ with $n+m$ variables and $4 m$ clauses.

## The Permanent

## Definition (PERMANENT)

For a $n \times n$ matrix $A$, the permanent of $A$ is:

$$
\operatorname{perm}(A)=\sum_{\sigma \in S_{n}} \prod_{i=1}^{n} A_{i, \sigma(i)}
$$

- Permanent is similar to the determinant, but it seems more difficult to compute.
- Combinatorial interpretation: If $A$ has entries $\in\{0,1\}$, it can be viewed as the adjacency matrix of a bipartite graph $G(X, Y, E)$ with $X=\left\{x_{1}, \ldots, x_{n}\right\}, Y=\left\{y_{1}, \ldots, y_{n}\right\}$ and $\left\{x_{i}, y_{j}\right\} \in E$ iff $A_{i, j}=1$.

## The Permanent

## Definition (PERMANENT)

For a $n \times n$ matrix $A$, the permanent of $A$ is:

$$
\operatorname{perm}(A)=\sum_{\sigma \in S_{n}} \prod_{i=1}^{n} A_{i, \sigma(i)}
$$

- Permanent is similar to the determinant, but it seems more difficult to compute.
- Combinatorial interpretation: If $A$ has entries $\in\{0,1\}$, it can be viewed as the adjacency matrix of a bipartite graph $G(X, Y, E)$ with $X=\left\{x_{1}, \ldots, x_{n}\right\}, Y=\left\{y_{1}, \ldots, y_{n}\right\}$ and $\left\{x_{i}, y_{j}\right\} \in E$ iff $A_{i, j}=1$.
- The term $\prod_{i=1}^{n} A_{i, \sigma(i)}$ is 1 iff $\sigma$ has a perfect matching.

## The Permanent

## Definition (PERMANENT)

For a $n \times n$ matrix $A$, the permanent of $A$ is:

$$
\operatorname{perm}(A)=\sum_{\sigma \in S_{n}} \prod_{i=1}^{n} A_{i, \sigma(i)}
$$

- Permanent is similar to the determinant, but it seems more difficult to compute.
- Combinatorial interpretation: If $A$ has entries $\in\{0,1\}$, it can be viewed as the adjacency matrix of a bipartite graph $G(X, Y, E)$ with $X=\left\{x_{1}, \ldots, x_{n}\right\}, Y=\left\{y_{1}, \ldots, y_{n}\right\}$ and $\left\{x_{i}, y_{j}\right\} \in E$ iff $A_{i, j}=1$.
- The term $\prod_{i=1}^{n} A_{i, \sigma(i)}$ is 1 iff $\sigma$ has a perfect matching.
- So, in this case perm $(A)$ is the number of perfect matchings in the corresponding graph!

## Valiant's Theorem

Theorem (Valiant's Theorem)
PERMANENT is \#P-complete under Cook reductions.

## The Class $\oplus \mathbf{P}$

## Definition

A language $L$ is in the class $\oplus \mathbf{P}$ if there is a NDTM $M$ such that for all strings $x, x \in L$ iff the number of accepting paths on input $x$ is odd.

- The problems $\oplus$ SAT and $\oplus$ HAMILTON PATH are $\oplus \mathbf{P}$-complete.
- $\oplus \mathbf{P}$ is closed under complement.
- $\oplus \mathbf{P}^{\oplus \mathbf{P}}=\oplus \mathbf{P}$

## Operators on Complexity Classes

- So far, we 've defined a lot of operators on complexity classes. We will remind them, and define some new in the same way:

Definition (Non-Deterministic Operator)
Let $\mathbf{C}$ be a complexity class. A language $L \in \mathcal{N}$. $\mathbf{C}$ if there exists $A \in \mathbf{C}$ such that:

- $x \in L \Rightarrow \exists y: x ; y \in A$
- $x \notin L \Rightarrow \forall y: x ; y \notin A$
- If $\mathbf{C}$ can be expressed using quantifier notation, then the $\mathcal{N}$. operator adds a $(\exists \cdot / \forall \cdot)$ in front of it.

> Example
> $\mathcal{N} \cdot \mathbf{P}=\mathbf{N P}$
> $\mathcal{N} \cdot \Pi_{i-1}^{p}=\Sigma_{i}^{p}$
> $\mathcal{N} \cdot \mathbf{B P P}=\mathbf{M A}$

## Operators on Complexity Classes

Definition (Two-sided Probabilistic Operator)
Let $\mathbf{C}$ be a complexity class. A language $L \in \mathcal{B P}$. $\mathbf{C}$ if there exists $A \in \mathbf{C}$ such that:

- $x \in L \Rightarrow \exists^{+} y: x ; y \in A$
- $x \notin L \Rightarrow \exists^{+} y: x ; y \notin A$

## Example

$\mathcal{B P} \cdot \mathbf{P}=\mathbf{B P P}, \mathcal{B P} \cdot \mathbf{N P}=\mathbf{A M}$
Definition (One-sided Probabilistic Operator)
Let $\mathbf{C}$ be a complexity class. A language $L \in \mathcal{R}$. $\mathbf{C}$ if there exists $A \in \mathbf{C}$ such that:

- $x \in L \Rightarrow \exists^{+} y: x ; y \in A$
- $x \notin L \Rightarrow \forall y: x ; y \notin A$

## Operators on Complexity Classes

Definition
Let $\mathbf{C}$ be a complexity class. A language $L \in \oplus \cdot \mathbf{C}$ if there exists
$A \in \mathbf{C}$ such that:

$$
x \in L \Leftrightarrow|\{y: x ; y \in A\}| \text { is odd }
$$

## Example

$\oplus \cdot \mathbf{P}=\oplus \mathbf{P}$

## Remark

Note that the class $\mathbf{C}$ in the above definitions must be closed under padding.

## Valiant-Vazirani Theorem

Theorem (Valiant-Vazirani)
Given a Boolean Formula $\phi$ in CNF, it can be transformed by a probabilistic, polynomial-time algorithm to a formula $\phi^{\prime}$, such that:

- $\phi \in \mathrm{SAT} \Longrightarrow \operatorname{Pr}\left[\phi^{\prime} \in \oplus \mathrm{SAT}\right]>\frac{1}{p(|\phi|)}$
- $\phi \notin \mathrm{SAT} \Longrightarrow \phi^{\prime} \notin \oplus \mathrm{SAT}$

The above is equivalent with:
Theorem (Valiant-Vazirani)
$\mathbf{N P} \subseteq \mathcal{R} \cdot \oplus \mathbf{P}$

- It also implies that $\mathbf{N P} \subseteq \mathbf{R P}^{\text {USAT }}$, where USAT is the unique-satisfiability problem.

## Proof of Valiant-Vazirani Theorem

## Proof:

- Let $\phi=\phi\left(x_{1}, \ldots, x_{n}\right)$.
- Let $S$ be a random subset of $[n]=\{1, \ldots, n\}$. (uses $n$ random bits).
- Let $[S]=\oplus_{i \in S} x_{i}$.
- The reduction algorithm is the following:
- Input $\phi$.
- Guess Randomly $k \in\{0, \ldots, n-1\}$.
- Guess Randomly subsets $S_{1}, \ldots, S_{k+2} \subseteq[n]$.
- Output $\phi^{\prime}=\phi \wedge\left[S_{1}\right] \wedge\left[S_{2}\right] \wedge \cdots \wedge\left[S_{k+2}\right]$.

## Proof of Valiant-Vazirani Theorem

## Proof:

- Let $\phi=\phi\left(x_{1}, \ldots, x_{n}\right)$.
- Let $S$ be a random subset of $[n]=\{1, \ldots, n\}$. (uses $n$ random bits).
- Let $[S]=\oplus_{i \in S} x_{i}$.
- The reduction algorithm is the following:
- Input $\phi$.
- Guess Randomly $k \in\{0, \ldots, n-1\}$.
- Guess Randomly subsets $S_{1}, \ldots, S_{k+2} \subseteq[n]$.
- Output $\phi^{\prime}=\phi \wedge\left[S_{1}\right] \wedge\left[S_{2}\right] \wedge \cdots \wedge\left[S_{k+2}\right]$.
- With each addition of a subformula of the form $\left[S_{i}\right]$ to the conjunction, the number of satisfying assignments is halved, since for each assignment $b$ the probability that $b([S])=0$ is $1 / 2$.

## Proof of Valiant-Vazirani Theorem

## Proof (cont'd):

- These events are only pairwise indepedent.
- If $\phi$ is unsatisfiable, then $\phi^{\prime}$ is clearly unsatisfiable, therefore $\phi^{\prime} \notin \oplus$ SAT.
- If $\phi$ is satisfiable, let $m \geq 1$ the number of satisfying assignments.

## Proof of Valiant-Vazirani Theorem

## Proof (cont'd):

- These events are only pairwise indepedent.
- If $\phi$ is unsatisfiable, then $\phi^{\prime}$ is clearly unsatisfiable, therefore $\phi^{\prime} \notin \oplus$ SAT.
- If $\phi$ is satisfiable, let $m \geq 1$ the number of satisfying assignments.
- With probability $\geq 1 / n, k$ will be chosen so that: $2^{k} \leq m \leq 2^{k+1}$.
- For that fixed $k$, let $b$ be a fixed satisfying assignment of $\phi$.
- Since $\left[S_{i}\right]$ 's are chosen indepedently,

$$
\operatorname{Pr}\left[b\left(\phi^{\prime}\right)=1\right]=\frac{1}{2^{k+2}}
$$

## Proof of Valiant-Vazirani Theorem

## Proof (cont'd):

- Even if $b$ "survived " the conjunction process, the probability that any other satisfying assignment $b^{\prime}$ of $\phi$ also survives the conjuction is also $1 / 2^{k+2}$.
- The probability that $b$ is the only formula that survives the conjuction (cf. USAT):

$$
\begin{gathered}
\frac{1}{2^{k+2}} \cdot\left(1-\sum_{b^{\prime}} \frac{1}{2^{k+2}}\right)=\frac{1}{2^{k+2}} \cdot\left(1-\frac{m-1}{2^{k+2}}\right) \geq \\
\geq \frac{1}{2^{k+2}} \cdot\left(1-\frac{2^{k+1}}{2^{k+2}}\right)=\frac{1}{2^{k+3}}
\end{gathered}
$$

## Proof of Valiant-Vazirani Theorem

## Proof (cont'd):

- Thus, the probability that there is a $b$ that is the only satisfying assignment of $\phi^{\prime}$ is at least:

$$
\sum_{b} \frac{1}{2^{k+3}}=\frac{m}{2^{k+3}} \geq \frac{2^{k}}{2^{k+3}}=\frac{1}{8}
$$

- So, we proved that for this choice of $k$, the probability is at least $1 / 8$.
- Thus,

$$
\operatorname{Pr}\left[\phi^{\prime} \notin \oplus \mathrm{SAT}\right] \geq \frac{1}{n} \cdot \frac{1}{8}=\frac{1}{8 n}
$$

Toda's Theorem

## Quantifiers vs Counting

- An imporant open question in the 80 s concerned the relative power of Polynomial Hierarchy and \#P.
- Both are natural generalizations of NP, but it seemed that their features were not directly comparable to each other.
- But, in $1989, \mathrm{~S}$. Toda showed the following theorem:

Toda's Theorem

## Quantifiers vs Counting

- An imporant open question in the 80 s concerned the relative power of Polynomial Hierarchy and \#P.
- Both are natural generalizations of NP, but it seemed that their features were not directly comparable to each other.
- But, in 1989, S. Toda showed the following theorem:

Theorem (Toda's Theorem)

$$
\mathbf{P H} \subseteq \mathbf{P}^{\# \mathbf{P}[1]}
$$

Toda's Theorem

## Proof of Toda's Theorem

- The proof consists of two main lemmas:

Toda's Theorem

## Proof of Toda's Theorem

- The proof consists of two main lemmas:

## Lemma 1

$\mathbf{P H} \subseteq \mathcal{B P} \cdot \oplus \mathbf{P}$

## Proof of Toda's Theorem

- The proof consists of two main lemmas:

Lemma 1
$\mathbf{P H} \subseteq \mathcal{B P} \cdot \oplus \mathbf{P}$

Lemma 2

$$
\mathcal{B P} \cdot \oplus \mathbf{P} \subseteq \mathbf{P} \# \mathbf{P}
$$

## Proof of Toda's Theorem

Lemma 1.1

$$
\oplus \cdot \oplus \cdot \mathbf{C}=\oplus \cdot \mathbf{C}
$$

## Proof

- Let $L \in \mathbf{C}, L^{\prime} \in \oplus \cdot \mathbf{C}$ and $L^{\prime \prime} \in \oplus \cdot \oplus \cdot \mathbf{C}$.
- $x \in Ł^{\prime \prime} \Leftrightarrow\left|\left\{y_{1}: x ; y_{1} \in L^{\prime}\right\}\right|$ is odd $\Leftrightarrow \sum_{y_{1}} L^{\prime}\left(x ; y_{1}\right) \equiv 1 \bmod 2$
$\Leftrightarrow \sum_{y_{1}} \sum_{y_{2}} L\left(x ; y_{1} ; y_{2}\right) \equiv 1 \bmod 2$
$\Leftrightarrow \sum_{y_{1}, y_{2}} L\left(x ; y_{1} ; y_{2}\right) \equiv 1 \bmod 2$
$\Leftrightarrow\left|\left\{y_{1} ; y_{2}: x ; y_{1} ; y_{2} \in L\right\}\right|$ is odd $\Leftrightarrow x \in L^{\prime}$

## Proof of Toda's Theorem

Lemma 1.2

$$
\mathcal{B P} \cdot \mathcal{B P} \cdot \mathbf{C} \subseteq \mathcal{B P} \cdot \mathbf{C}
$$

## Proof:

Easy exercise :)

## Proof of Toda's Theorem

Lemma 1.2

$$
\mathcal{B P} \cdot \mathcal{B P} \cdot \mathbf{C} \subseteq \mathcal{B P} \cdot \mathbf{C}
$$

## Proof:

Easy exercise :)

Lemma 1.3
$\oplus \cdot \mathcal{B P} \cdot \mathbf{C} \subseteq \mathcal{B P} \cdot \oplus \cdot \mathbf{C}$

## Toda's Theorem

## Proof of Toda's Theorem

Lemma 1.3

$$
\oplus \cdot \mathcal{B P} \cdot \mathbf{C} \subseteq \mathcal{B P} \cdot \oplus \cdot \mathbf{C}
$$

## Proof:

- Let $L \in \oplus \cdot \mathcal{B P} \cdot \mathbf{C}$.
- Then $\exists A \in \mathcal{B P}$. $\mathbf{C}$, such that:

$$
x \in L \Leftrightarrow\left|\left\{z:|z|=|x|^{k} \wedge x ; z \in A\right\}\right| \text { is odd }
$$

- Then, $\exists B \in \mathbf{C}$, such that:

$$
\operatorname{Pr}_{w}\left[\exists z \in\{0,1\}^{|x|^{k}}: x ; z ; w \in B \Leftrightarrow x ; z \notin A\right] \leq \frac{1}{3}
$$

## Proof of Toda＇s Theorem

Proof（cont＇d）：
－Let $B^{\prime}=\{x ; w ; z: x ; z ; w \in B\} \in \mathbf{C}$ ．
－Let $B^{\prime \prime}=\left\{x ; w:\left|\left\{z:|z|=|x|^{k} \wedge x ; w ; z \in B^{\prime}\right\}\right|\right.$ is odd $\} \in \oplus \cdot \mathbf{C}$ ．
－$x \in L \Rightarrow\left|\left\{z:|z|=|x|^{k} \wedge x ; z \in A\right\}\right|$ is odd
$\Rightarrow \operatorname{Pr}_{w}\left[\left|\left\{z:|z|=|x|^{k} \wedge x ; z ; w \in B\right\}\right|\right.$ is odd $] \geq \frac{2}{3}$
$\Rightarrow \operatorname{Pr}_{w}\left[x ; w \in B^{\prime \prime}\right] \geq \frac{2}{3}$
－$x \notin L \Rightarrow\left|\left\{z:|z|=|x|^{k} \wedge x ; z \in A\right\}\right|$ is even
$\Rightarrow \operatorname{Pr}_{w}\left[\left|\left\{z:|z|=|x|^{k} \wedge x ; z ; w \in B\right\}\right|\right.$ is odd $] \leq \frac{1}{3}$
$\Rightarrow \operatorname{Pr}_{w}\left[x ; w \in B^{\prime \prime}\right] \leq \frac{1}{3}$
－Hence，$L \in \mathbf{B P} \cdot \oplus \cdot \mathbf{C}$ ．

## Proof of Toda's Theorem

Lemma 1.4

$$
\mathcal{N} \cdot \mathbf{C} \subseteq \mathcal{B P} \cdot \oplus \cdot \mathbf{C}
$$

## Proof Idea:

- That is, essentially, a generalization of Valiant-Vazirani Theorem:
- Instead of SAT, we could use $\Sigma_{k}^{p}$-complete version of $\mathrm{SAT}_{k}$ and prove with slight modifications that:

$$
\Sigma_{k}^{p}=\mathcal{N} \cdot \Pi_{k-1}^{p} \subseteq \mathcal{B P} \cdot \oplus \cdot \Pi_{k-1}^{p}
$$

## Proof of Toda's Theorem

## Lemma 1

## $\mathbf{P H} \subseteq \mathcal{B P} \cdot \oplus \mathbf{P}$

Proof (of Lemma 1):

- We will prove by induction that $\Sigma_{k}^{p}, \Pi_{k}^{p} \subseteq \mathcal{B P} \cdot \oplus \cdot \mathbf{P}$
- The base $k=0$ is trivial, since $\mathbf{P} \subseteq \mathcal{B P} \cdot \oplus \cdot \mathbf{P}$.
- The induction hypothesis states that $\sum_{k-1}^{p}, \Pi_{k-1}^{p} \subseteq \mathcal{B P} \cdot \oplus \cdot \mathbf{P}$.
- Then:

$$
\begin{gathered}
\Sigma_{k}^{p}=\mathcal{N} \cdot \Pi_{k-1} \subseteq \mathcal{B P} \cdot \oplus \cdot \Pi_{k-1}^{p} \subseteq \mathcal{B P} \cdot \oplus \cdot \mathcal{B P} \cdot \oplus \cdot \mathbf{P} \\
\subseteq \mathcal{B P} \cdot \mathcal{B P} \cdot \oplus \cdot \oplus \cdot \mathbf{P} \subseteq \mathcal{B P} \cdot \oplus \cdot \mathbf{P}
\end{gathered}
$$

## Proof of Toda's Theorem

Lemma 2

$$
\mathcal{B P} \cdot \oplus \mathbf{P} \subseteq \mathbf{P}^{\# \mathbf{P}}
$$

## Proof Sketch:

- Let $L \in \mathcal{B P} \cdot \oplus \mathbf{P}$
- So, $\exists A \in \oplus \mathbf{P}$, such that:

$$
\operatorname{Pr}_{y}[x \in L \Leftrightarrow x ; y \in A] \geq \frac{2}{3}
$$

## Toda's Theorem

## Proof of Toda's Theorem

Amplification Example

- Example mod 8.
- We want to modify this tree to another s.t.:
- Odd number of $z^{\prime} s \Longrightarrow$ number of $z^{\prime \prime} s \equiv 0 \bmod 8$
- Even number of $z^{\prime} s \Longrightarrow$ number of $z^{\prime \prime} s \equiv 1 \bmod 8$

## Proof of Toda's Theorem

Amplification Example

- Example mod 8.
- We want to modify this tree to another s.t.:
- Odd number of $z^{\prime} s \Longrightarrow$ number of $z^{\prime \prime} s \equiv 0 \bmod 8$
- Even number of $z^{\prime} s \Longrightarrow$ number of $z^{\prime \prime} s \equiv 1 \bmod 8$

## Proof of Toda's Theorem

## Amplification Example

- Example mod 8.
- We want to modify this tree to another s.t.:
- Odd number of $z^{\prime} s \Longrightarrow$ number of $z^{\prime \prime} s \equiv 0 \bmod 8$
- Even number of $z^{\prime} s \Longrightarrow$ number of $z^{\prime \prime} s \equiv 1 \bmod 8$

## Proof of Toda's Theorem

- Now, let $g=g(x)$ be the number of accepting computations:
- If $g \equiv 0 \bmod 8$ or $g \equiv 1 \bmod 8$, then $x \in A$.
- If $g \equiv 3 \bmod 8$ or $g \equiv 4 \bmod 8$, then $x \notin A$.
- We can generalize this so that:

$$
x \in A \Leftrightarrow g<\frac{2^{p(|x|)}}{2} \quad \bmod 2^{p(|x|)}
$$

Lemma 2.1
For $A \in \oplus \mathbf{P}$, and $\forall p \in \operatorname{poly}(n), \exists$ PNTM $M$ :

- $x \in A \Rightarrow \# \operatorname{acc}_{M}(x) \equiv 0 \bmod 2^{p(n)}$
- $x \notin A \Rightarrow \# \operatorname{acc}_{M}(x) \equiv 1 \bmod 2^{p(n)}$

## Toda's Theorem

## Proof of Toda's Theorem

- Let:

$$
\begin{gathered}
h(x)=\sum_{y,|y|=p(|x|)} \# a c c_{M}(x ; y) \\
=\sum_{x ; y \in A} \# \operatorname{acc}(x ; y)+\sum_{x: y \notin A} \# a c c_{M}(x ; y) \\
\equiv-g(x) \quad \bmod ^{p(n)}
\end{gathered}
$$

- So, we can decide $x \in L$ from $h(x)$.
- But, $h \in \# \mathbf{P}$ : on input $x$, guess a $y,|y|=p(|x|)$, and simulate $M$ on $x ; y$.
- Hence $L \in \mathbf{P}^{\# \mathbf{P}[1]}$.

## The Class GapP

- For a TM M, we define:

$$
\Delta M(x)=\# \operatorname{acc}(x)-\# \operatorname{rej}(x)=\# M(x)-\# \bar{M}(x)
$$

Definition
A function $f:\{0,1\}^{*} \rightarrow \mathbb{N}$ is in GapP if there exists a poly-time NDTM $M$ such that for all inputs $x$ :

$$
f(x)=\Delta M(x)
$$

- GapP functions are closed under negation: $f \in \mathbf{G a p} \mathbf{P} \Rightarrow-f \in \mathbf{G a p} \mathbf{P}$.
- GapP, unlike \#P, encompasses all FP functions.

## The Class GapP

Theorem
For all functions $f$, the following are equivalent:
(1) $f \in \mathbf{G a p P}$.

2 $f$ is the difference of two \# $\mathbf{P}$ functions.
3 is the difference of a \#P and an FP function.
${ }^{4} f$ is the difference of a FP and an \#P function.
In other words:

$$
\mathbf{G a p} \mathbf{P}=\# \mathbf{P}-\# \mathbf{P}=\# \mathbf{P}-\mathbf{F P}=\mathbf{F P}-\# \mathbf{P}
$$

- $(3) \Rightarrow \mathbf{G a p} \mathbf{P} \subseteq \mathbf{F P}^{\# \mathbf{P}}[1]$.

## Characterizations of Complexity Classes

- NP consists of those languages $L$ such that for some \#P function $f$ and all inputs $x$ :
- If $x \in L$ then $f(x)>0$.
- If $x \notin L$ then $f(x)=0$.
- UP consists of those languages $L$ such that for some \#P function $f$ and all inputs $x$ :
- If $x \in L$ then $f(x)=1$.
- If $x \notin L$ then $f(x)=0$.
- PP consists of those languages $L$ such that for some GapP function $f$ and all inputs $x$ :
- If $x \in L$ then $f(x)>0$.
- If $x \notin L$ then $f(x) \leq 0$ (of $f(x)<0$ ).
- SPP consists of those languages $L$ such that for some GapP function $f$ and all inputs $x$ :
- If $x \in L$ then $f(x)=1$.
- If $x \notin L$ then $f(x)=0$.

## Characterizations of Complexity Classes

- $\mathbf{C}_{=} \mathbf{P}$ consists of those languages $L$ such that for some GapP function $f$ and all inputs $x$ :
- If $x \in L$ then $f(x)=0$.
- If $x \notin L$ then $f(x) \neq 0$ (or $f(x)>0$ ).
- $\oplus \mathbf{P}$ consists of those languages $L$ such that for some \# $\mathbf{P}$ function $f$ and all inputs $x$ :
- If $x \in L$ then $f(x)$ is odd.
- If $x \notin L$ then $f(x)$ is even.
- $\mathbf{M o d}_{\mathbf{k}} \mathbf{P}$ consists of those languages $L$ such that for some \#P function $f$ and all inputs $x$ :
- If $x \in L$ then $f(x) \bmod k \neq 0$.
- If $x \notin L$ then $f(x) \bmod k=0$.
- MiddleP consists of those languages $L$ such that for some \#P function $f$ and all inputs $x$ :
- If $x \in L$ then $\operatorname{middle}(f(x))=1$.
- If $x \notin L$ then $\operatorname{middle}(f(x))=0$.

## Characterizations of Complexity Classes

- We can summarize the above:

| Class | Function $f$ in: | If $x \in L:$ | If $x \notin L$ : |
| :--- | :--- | :--- | :--- |
| NP | \#P | $f(x)>0$ | $f(x)=0$ |
| UP | \#P | $f(x)=1$ | $f(x)=0$ |
| $\mathbf{P P}$ | GapP | $f(x)>0$ | $f(x) \leq 0$ or $f(x)<0$ |
| SPP | GapP | $f(x)=1$ | $f(x)=0$ |
| $\mathbf{C}=\mathbf{P}$ | GapP | $f(x)=0$ | $f(x) \neq 0$ or $f(x)>0$ |
| $\oplus \mathbf{P}$ | \#P | $f(x)$ is odd | $f(x)$ is even |
| Mod $\mathbf{k} \mathbf{P}$ | \#P | $f(x) \bmod k \neq 0$ | $f(x) \bmod k=0$ |
| MiddleP | \#P | middle $(f(x))=1$ | middle $(f(x))=0$ |

## Characterizations of Complexity Classes

- We define middle: : $\{0,1\}^{*} \rightarrow\{0,1\}$ to return the $\left\lceil\frac{|x|}{2}\right\rceil^{\text {th }}$ bit of the string $x$.
- The class MiddleP considers the middle bit of a string, as $\mathbf{P P}$ consider the high-order bit and $\oplus \mathbf{P}$ the low-order bit.
- Observe that $\oplus \mathbf{P}=\mathbf{M o d}_{2} \mathbf{P}$.
- From the above we can easily have:
- $\mathbf{N P} \subseteq c^{\prime} \mathbf{C}_{=} \mathbf{P} \subseteq \mathbf{P P}$
- $\mathbf{U P} \subseteq \mathbf{S P P}$
- $\mathbf{C}=\mathbf{P} \subseteq \mathbf{P P}$
- PP is closed under complement.

## Characterizations of Complexity Classes

Theorem

$$
\mathbf{P}^{\mathbf{P P}}=\mathbf{P}^{\mathbf{G a p P}}
$$

Proof:

- We only need to show that every GapP function $g$ is computable in FP ${ }^{\text {PP }}$.
- Consider the GapP function $f(x, k)=g(x)-k$.
- Then $L=\{\langle x, k\rangle: g(x)>k\} \in \mathbf{P P}$, by the previous classification.
- Use binary search using $L$ as an oracle to find the value of $g(x)$.
