- It means that if we had an oracle that could instantly respond to any query about whether or not a given string is in T , then we would be able to recognize S in polynomial time, deterministically.
- It is assumed that all strings contain characters from a fixed, finite alphabet Σ , which is unspecified, but large enough to contain every necessary character.

Definition

A query machine is a multitape Turing machine with a distinguished tape called the query tape and three distinguished states called the query state, yes state, and no state, respectively. If M is a query machine and T is a set of strings, then a T -computation of M is a computation of M in which initially M is in the initial state and has an input string w on its input tape and each time M assumes the query state there is a string u on the query tape and the next state M assumes is the yes state if $u \in T$ and the no state if $u \notin T$. We think of an “oracle”, which knows T , placing M in the yes state or no state.

Proof of the Theorem:

What we have: Nondeterministic Turing machine M , which accepts S in time $Q(n)$, and input w .

What we want: A formula in DNF such that the input is in S iff the formula is not a tautology.

Method: We will define a formula $A(w)$ in CNF, which is satisfiable iff M accepts w . Then $\neg A(w)$ can be put in DNF using De Morgan's laws and $w \in S$ iff $A(w)$ is not a tautology.

- $G = \bigwedge_{t=1}^T \bigwedge_{i=1}^r \bigwedge_{j=1}^l G_{i,j}^t$
 - $G_{i,j}^t = \bigwedge_{s=1}^T \left(\neg Q_t^i \vee \neg S_{s,t} \vee \neg P_{s,t}^j \vee Q_{t+1}^k \right)$ (where q_k is the state given by M 's transition function at (q_i, σ_j))
- $H = \bigwedge_{t=1}^T \bigwedge_{i=1}^r \bigwedge_{j=1}^l H_{i,j}^t$
 - $H_{i,j}^t = \bigwedge_{s=1}^T \left(\neg Q_t^i \vee \neg S_{s,t} \vee \neg P_{s,t}^j \vee S_{k,t}^k \right)$ (where k is the tape cell to which M 's head must move, according to M 's transition function at (q_i, σ_j))
- $I = \bigvee_{t=1}^T Q_t^r$

Note: There appears to be a slight omission, regarding the nondeterministic nature of M (it has a transition relation, not function). However, this should not affect the correctness of the results.

Theorem

The following sets are P-reducible to each other in pairs (and hence they have the same polynomial degree of difficulty):
{tautologies}, {DNF tautologies}, D_3 , {subgraph pairs}.

Steps of the proof:

- By the corollary to the first Theorem, each of the sets is P-reducible to {DNF tautologies}.

Main Results

Definition

Given a machine M_Q and recursive function $T_Q(k)$, we will say M_Q is of type Q and runs within time $T_Q(k)$ provided that, when M_Q starts with a predicate formula A written on its tape, M_Q halts if and only if A is unsatisfiable and for all k , if $\phi(A) \leq k$ and $|A| \leq \log_2 k$, then M_Q halts within $T_Q(k)$ steps. In this case we will also say that $T_Q(k)$ is of type Q . Here $|A|$ is the length of A .

Efficiency of Theorem Proving Procedures

Theorem

A) For any $T_Q(k)$ of type Q ,

$$\frac{T_Q(k)}{\sqrt{k} \log^2 k}$$

is unbounded.

B) There is a $T_Q(k)$ of type Q , such that

$$T_Q(k) \leq k 2^{k \log^2 k}.$$

Theorem

If a set S of strings is accepted by a nondeterministic machine within time $T(n) = 2^n$ and if $T_Q(k)$ is an honest (i.e. real-time countable) function of type Q , then there is a constant K , such that S can be recognized by a deterministic machine within time $T_Q(K8^n)$.
